**STM32F405/415, STM32F407/417, STM32F427/437 and  
STM32F429/439 advanced Arm<sup>®</sup>-based 32-bit MCUs**

---

## **Introduction**

This reference manual targets application developers. It provides complete information on how to use the STM32F405xx/07xx, STM32F415xx/17xx, STM32F42xxx and STM32F43xxx microcontroller memory and peripherals.

The STM32F405xx/07xx, STM32F415xx/17xx, STM32F42xxx and STM32F43xxx constitute a family of microcontrollers with different memory sizes, packages and peripherals.

For ordering information, mechanical and electrical device characteristics please refer to the datasheets.

For information on the Arm<sup>®</sup> Cortex<sup>®</sup>-M4 with FPU core, please refer to the *Cortex<sup>®</sup>-M4 with FPU Technical Reference Manual*.

## List of tables

|           |                                                                                                                |     |
|-----------|----------------------------------------------------------------------------------------------------------------|-----|
| Table 1.  | STM32F4xx register boundary addresses .....                                                                    | 64  |
| Table 2.  | Boot modes .....                                                                                               | 69  |
| Table 3.  | Memory mapping vs. Boot mode/physical remap<br>in STM32F405xx/07xx and STM32F415xx/17xx .....                  | 71  |
| Table 4.  | Memory mapping vs. Boot mode/physical remap<br>in STM32F42xxx and STM32F43xxx .....                            | 71  |
| Table 5.  | Flash module organization (STM32F40x and STM32F41x) .....                                                      | 75  |
| Table 6.  | Flash module - 2 Mbyte dual bank organization (STM32F42xxx and STM32F43xxx) ....                               | 77  |
| Table 7.  | 1 Mbyte Flash memory single bank vs dual bank organization<br>(STM32F42xxx and STM32F43xxx) .....              | 78  |
| Table 8.  | 1 Mbyte single bank Flash memory organization<br>(STM32F42xxx and STM32F43xxx) .....                           | 78  |
| Table 9.  | 1 Mbyte dual bank Flash memory organization (STM32F42xxx and STM32F43xxx) ....                                 | 79  |
| Table 10. | Number of wait states according to CPU clock (HCLK) frequency<br>(STM32F405xx/07xx and STM32F415xx/17xx) ..... | 80  |
| Table 11. | Number of wait states according to CPU clock (HCLK) frequency<br>(STM32F42xxx and STM32F43xxx) .....           | 81  |
| Table 12. | Program/erase parallelism .....                                                                                | 85  |
| Table 13. | Flash interrupt request .....                                                                                  | 88  |
| Table 14. | Option byte organization .....                                                                                 | 88  |
| Table 15. | Description of the option bytes (STM32F405xx/07xx and STM32F415xx/17xx) .....                                  | 89  |
| Table 16. | Description of the option bytes<br>(STM32F42xxx and STM32F43xxx) .....                                         | 90  |
| Table 17. | Access versus read protection level .....                                                                      | 94  |
| Table 18. | OTP area organization .....                                                                                    | 97  |
| Table 19. | Flash register map and reset values<br>(STM32F405xx/07xx and STM32F415xx/17xx) .....                           | 111 |
| Table 20. | Flash register map and reset values (STM32F42xxx and STM32F43xxx) .....                                        | 111 |
| Table 21. | CRC calculation unit register map and reset values .....                                                       | 115 |
| Table 22. | Voltage regulator configuration mode versus device operating mode .....                                        | 122 |
| Table 23. | Low-power mode summary .....                                                                                   | 128 |
| Table 24. | Sleep-now entry and exit .....                                                                                 | 129 |
| Table 25. | Sleep-on-exit entry and exit .....                                                                             | 130 |
| Table 26. | Stop operating modes<br>(STM32F405xx/07xx and STM32F415xx/17xx) .....                                          | 131 |
| Table 27. | Stop mode entry and exit (for STM32F405xx/07xx and STM32F415xx/17xx) .....                                     | 132 |
| Table 28. | Stop operating modes (STM32F42xxx and STM32F43xxx) .....                                                       | 134 |
| Table 29. | Stop mode entry and exit (STM32F42xxx and STM32F43xxx) .....                                                   | 136 |
| Table 30. | Standby mode entry and exit .....                                                                              | 137 |
| Table 31. | PWR - register map and reset values for STM32F405xx/07xx and STM32F415xx/17xx. ....                            | 149 |
| Table 32. | PWR - register map and reset values for STM32F42xxx and STM32F43xxx .....                                      | 149 |
| Table 33. | RCC register map and reset values for STM32F42xxx and STM32F43xxx .....                                        | 210 |
| Table 34. | RCC register map and reset values .....                                                                        | 265 |
| Table 35. | Port bit configuration table .....                                                                             | 268 |
| Table 36. | Flexible SWJ-DP pin assignment .....                                                                           | 271 |
| Table 37. | RTC_AF1 pin .....                                                                                              | 279 |
| Table 38. | RTC_AF2 pin .....                                                                                              | 280 |
| Table 39. | GPIO register map and reset values .....                                                                       | 287 |

|           |                                                                              |     |
|-----------|------------------------------------------------------------------------------|-----|

# 1 Documentation conventions

The STM32F401xx devices have an Arm<sup>®(a)</sup> Cortex<sup>®</sup>-M4 with FPU.

## 1.1 List of abbreviations for registers

The following abbreviations are used in register descriptions:

|                                |                                                                                                                          |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| read/write (rw)                | Software can read and write to these bits.                                                                               |
| read-only (r)                  | Software can only read these bits.                                                                                       |
| write-only (w)                 | Software can only write to this bit. Reading the bit returns the reset value.                                            |
| read/clear (rc_w1)             | Software can read as well as clear this bit by writing 1. Writing '0' has no effect on the bit value.                    |
| read/clear (rc_w0)             | Software can read as well as clear this bit by writing 0. Writing '1' has no effect on the bit value.                    |
| read/clear by read (rc_r)      | Software can read this bit. Reading this bit automatically clears it to '0'. Writing '0' has no effect on the bit value. |
| read/set (rs)                  | Software can read as well as set this bit. Writing '0' has no effect on the bit value.                                   |
| read-only write trigger (rt_w) | Software can read this bit. Writing '0' or '1' triggers an event but has no effect on the bit value.                     |
| toggle (t)                     | Software can only toggle this bit by writing '1'. Writing '0' has no effect.                                             |
| Reserved (Res.)                | Reserved bit, must be kept at reset value.                                                                               |

## 1.2 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- The CPU core integrates two debug ports:
  - JTAG debug port (JTAG-DP) provides a 5-pin standard interface based on the Joint Test Action Group (JTAG) protocol.
  - SWD debug port (SWD-DP) provides a 2-pin (clock and data) interface based on the Serial Wire Debug (SWD) protocol.

For both the JTAG and SWD protocols, please refer to the Cortex<sup>®</sup>-M4 with FPU Technical Reference Manual
- Word: data/instruction of 32-bit length.
- Half word: data/instruction of 16-bit length.
- Byte: data of 8-bit length.
- Double word: data of 64-bit length.
- IAP (in-application programming): IAP is the ability to reprogram the Flash memory of a microcontroller while the user program is running.
- ICP (in-circuit programming): ICP is the ability to program the Flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- I-Code: this bus connects the Instruction bus of the CPU core to the Flash instruction interface. Prefetch is performed on this bus.
- D-Code: this bus connects the D-Code bus (literal load and debug access) of the CPU to the Flash data interface.
- Option bytes: product configuration bits stored in the Flash memory.
- OBL: option byte loader.
- AHB: advanced high-performance bus.
- CPU: refers to the Cortex<sup>®</sup>-M4 with FPU core.

## 1.3 Peripheral availability

For peripheral availability and number across all STM32F405xx/07xx and STM32F415xx/17xx sales types, please refer to the STM32F405xx/07xx and STM32F415xx/17xx datasheets.

For peripheral availability and number across all STM32F42xxx and STM32F43xxx sales types, please refer to the STM32F42xxx and STM32F43xxx datasheets.

## 2 Memory and bus architecture

### 2.1 System architecture

In STM32F405xx/07xx and STM32F415xx/17xx, the main system consists of 32-bit multilayer AHB bus matrix that interconnects:

The main system consists of 32-bit multilayer AHB bus matrix that interconnects:

- Eight masters:
  - Cortex<sup>®</sup>-M4 with FPU core I-bus, D-bus and S-bus
  - DMA1 memory bus
  - DMA2 memory bus
  - DMA2 peripheral bus
  - Ethernet DMA bus
  - USB OTG HS DMA bus
- Seven slaves:
  - Internal Flash memory ICode bus
  - Internal Flash memory DCode bus
  - Main internal SRAM1 (112 KB)
  - Auxiliary internal SRAM2 (16 KB)
  - AHB1 peripherals including AHB to APB bridges and APB peripherals
  - AHB2 peripherals
  - FSMC

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. The 64-Kbyte CCM (core coupled memory) data RAM is not part of the bus matrix and can be accessed only through the CPU. This architecture is shown in [Figure 1](#).

Figure 1. System architecture for STM32F405xx/07xx and STM32F415xx/17xx devices

In the STM32F42xx and STM32F43xx devices, the main system consists of 32-bit multilayer AHB bus matrix that interconnects:

- Ten masters:
  - Cortex<sup>®</sup>-M4 with FPU core I-bus, D-bus and S-bus
  - DMA1 memory bus
  - DMA2 memory bus
  - DMA2 peripheral bus
  - Ethernet DMA bus
  - USB OTG HS DMA bus
  - LCD Controller DMA-bus
  - DMA2D (Chrom-Art Accelerator™) memory bus
- Eight slaves:
  - Internal Flash memory ICode bus
  - Internal Flash memory DCode bus
  - Main internal SRAM1 (112 KB)
  - Auxiliary internal SRAM2 (16 KB)
  - Auxiliary internal SRAM3 (64 KB)
  - AHB1 peripherals including AHB to APB bridges and APB peripherals
  - AHB2 peripherals
  - FMC

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. The 64-Kbyte CCM (core coupled memory) data RAM is not part of the bus matrix and can be accessed only through the CPU. This architecture is shown in [Figure 2](#).

Figure 2. System architecture for STM32F42xxx and STM32F43xxx devices

### 2.1.1 I-bus

This bus connects the Instruction bus of the Cortex<sup>®</sup>-M4 with FPU core to the BusMatrix. This bus is used by the core to fetch instructions. The target of this bus is a memory containing code (internal Flash memory/SRAM or external memories through the FSMC/FMC).

### 2.1.2 D-bus

This bus connects the databus of the Cortex<sup>®</sup>-M4 with FPU to the 64-Kbyte CCM data RAM to the BusMatrix. This bus is used by the core for literal load and debug access. The target of this bus is a memory containing code or data (internal Flash memory or external memories through the FSMC/FMC).

### 2.1.3 S-bus

This bus connects the system bus of the Cortex<sup>®</sup>-M4 with FPU core to a BusMatrix. This bus is used to access data located in a peripheral or in SRAM. Instructions may also be fetched on this bus (less efficient than ICode). The targets of this bus are the internal SRAM1, SRAM2 and SRAM3, the AHB1 peripherals including the APB peripherals, the AHB2 peripherals and the external memories through the FSMC/FMC.

#### **2.1.4 DMA memory bus**

This bus connects the DMA memory bus master interface to the BusMatrix. It is used by the DMA to perform transfer to/from memories. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2 and SRAM3) and external memories through the FSMC/FMC.

#### **2.1.5 DMA peripheral bus**

This bus connects the DMA peripheral master bus interface to the BusMatrix. This bus is used by the DMA to access AHB peripherals or to perform memory-to-memory transfers. The targets of this bus are the AHB and APB peripherals plus data memories: internal SRAMs (SRAM1, SRAM2 and SRAM3) and external memories through the FSMC/FMC.

#### **2.1.6 Ethernet DMA bus**

This bus connects the Ethernet DMA master interface to the BusMatrix. This bus is used by the Ethernet DMA to load/store data to a memory. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2, SRAM3), internal Flash memory, and external memories through the FSMC/FMC.

#### **2.1.7 USB OTG HS DMA bus**

This bus connects the USB OTG HS DMA master interface to the BusMatrix. This bus is used by the USB OTG DMA to load/store data to a memory. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2, SRAM3), internal Flash memory, and external memories through the FSMC/FMC.

#### **2.1.8 LCD-TFT controller DMA bus**

This bus connects the LCD controller DMA master interface to the BusMatrix. It is used by the LCD-TFT DMA to load/store data to a memory. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2, SRAM3), external memories through FMC, and internal Flash memory.

#### **2.1.9 DMA2D bus**

This bus connect the DMA2D master interface to the BusMatrix. This bus is used by the DMA2D graphic Accelerator to load/store data to a memory. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2, SRAM3), external memories through FMC, and internal Flash memory.

#### **2.1.10 BusMatrix**

The BusMatrix manages the access arbitration between masters. The arbitration uses a round-robin algorithm.

### 2.1.11 AHB/APB bridges (APB)

The two AHB/APB bridges, APB1 and APB2, provide full synchronous connections between the AHB and the two APB buses, allowing flexible selection of the peripheral frequency.

Refer to the device datasheets for more details on APB1 and APB2 maximum frequencies, and to [Table 1](#) for the address mapping of AHB and APB peripherals.

After each device reset, all peripheral clocks are disabled (except for the SRAM and Flash memory interface). Before using a peripheral you have to enable its clock in the RCC\_AHBxENR or RCC\_APBxENR register.

*Note:* When a 16- or an 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.

## 2.2 Memory organization

Program memory, data memory, registers and I/O ports are organized within the same linear 4 Gbyte address space.

The bytes are coded in memory in little endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte, the word's most significant.

For the detailed mapping of peripheral registers, please refer to the related chapters.

The addressable memory space is divided into 8 main blocks, each of 512 MB.

All the memory areas that are not allocated to on-chip memories and peripherals are considered "Reserved". Refer to the memory map figure in the product datasheet.

## 2.3 Memory map

See the datasheet corresponding to your device for a comprehensive diagram of the memory map. [Table 1](#) gives the boundary addresses of the peripherals available in all STM32F4xx devices.

**Table 1. STM32F4xx register boundary addresses**

| Boundary address          | Peripheral                                                                                                           | Bus  | Register map                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------|------|-------------------------------------------------------------------------------------------------------------------------------|
| 0xA000 0000 - 0xA000 0FFF | FSMC control register (STM32F405xx/07xx and STM32F415xx/17xx)/<br>FMC control register (STM32F42xxx and STM32F43xxx) | AHB3 | <a href="#">Section 36.6.9: FSMC register map on page 1600</a><br><a href="#">Section 37.8: FMC register map on page 1680</a> |

Table 1. STM32F4xx register boundary addresses (continued)

| Boundary address          | Peripheral               | Bus  | Register map                                                        |

### 2.3.1 Embedded SRAM

The STM32F405xx/07xx and STM32F415xx/17xx feature 4 Kbytes of backup SRAM (see [Section 5.1.2: Battery backup domain](#)) plus 192 Kbytes of system SRAM.

The STM32F42xxx and STM32F43xxx feature 4 Kbytes of backup SRAM (see [Section 5.1.2: Battery backup domain](#)) plus 256 Kbytes of system SRAM.

The embedded SRAM can be accessed as bytes, half-words (16 bits) or full words (32 bits). Read and write operations are performed at CPU speed with 0 wait state. The embedded SRAM is divided into up to three blocks:

- SRAM1 and SRAM2 mapped at address 0x2000 0000 and accessible by all AHB masters.
- SRAM3 (available on STM32F42xxx and STM32F43xxx) mapped at address 0x2002 0000 and accessible by all AHB masters.
- CCM (core coupled memory) mapped at address 0x1000 0000 and accessible only by the CPU through the D-bus.

The AHB masters support concurrent SRAM accesses (from the Ethernet or the USB OTG HS): for instance, the Ethernet MAC can read/write from/to SRAM2 while the CPU is reading/writing from/to SRAM1 or SRAM3.

The CPU can access the SRAM1, SRAM2, and SRAM3 through the System Bus or through the I-Code/D-Code buses when boot from SRAM is selected or when physical remap is selected ([Section 9.2.1: SYSCFG memory remap register \(SYSCFG\\_MEMRMP\)](#) in the SYSCFG controller). To get the max performance on SRAM execution, physical remap should be selected (boot or software selection).

### 2.3.2 Flash memory overview

The Flash memory interface manages CPU AHB I-Code and D-Code accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms. It accelerates code execution with a system of instruction prefetch and cache lines.

The Flash memory is organized as follows:

- A main memory block divided into sectors.
- System memory from which the device boots in System memory boot mode
- 512 OTP (one-time programmable) bytes for user data.
- Option bytes to configure read and write protection, BOR level, watchdog software/hardware and reset when the device is in Standby or Stop mode.

Refer to [Section 3: Embedded Flash memory interface](#) for more details.

### 2.3.3 Bit banding

The Cortex<sup>®</sup>-M4 with FPU memory map includes two bit-band regions. These regions map each word in an alias region of memory to a bit in a bit-band region of memory. Writing to a word in the alias region has the same effect as a read-modify-write operation on the targeted bit in the bit-band region.

In the STM32F4xx devices both the peripheral registers and the SRAM are mapped to a bit-band region, so that single bit-band write and read operations are allowed. The operations

are only available for Cortex®-M4 with FPU accesses, and not from other bus masters (e.g. DMA).

A mapping formula shows how to reference each word in the alias region to a corresponding bit in the bit-band region. The mapping formula is:

$$\text{bit\_word\_addr} = \text{bit\_band\_base} + (\text{byte\_offset} \times 32) + (\text{bit\_number} \times 4)$$

where:

- **bit\_word\_addr** is the address of the word in the alias memory region that maps to the targeted bit
- **bit\_band\_base** is the starting address of the alias region
- **byte\_offset** is the number of the byte in the bit-band region that contains the targeted bit
- **bit\_number** is the bit position (0-7) of the targeted bit

### Example

The following example shows how to map bit 2 of the byte located at SRAM address 0x20000300 to the alias region:

$$0x22006008 = 0x22000000 + (0x300 \times 32) + (2 \times 4)$$

Writing to address 0x22006008 has the same effect as a read-modify-write operation on bit 2 of the byte at SRAM address 0x20000300.

Reading address 0x22006008 returns the value (0x01 or 0x00) of bit 2 of the byte at SRAM address 0x20000300 (0x01: bit set; 0x00: bit reset).

For more information on bit-banding, please refer to the *Cortex®-M4 with FPU programming manual* (see [Related documents on page 1](#)).

## 2.4 Boot configuration

Due to its fixed memory map, the code area starts from address 0x0000 0000 (accessed through the ICode/DCode buses) while the data area (SRAM) starts from address 0x2000 0000 (accessed through the system bus). The Cortex®-M4 with FPU CPU always fetches the reset vector on the ICode bus, which implies to have the boot space available only in the code area (typically, Flash memory). STM32F4xx microcontrollers implement a special mechanism to be able to boot from other memories (like the internal SRAM).

In the STM32F4xx, three different boot modes can be selected through the BOOT[1:0] pins as shown in [Table 2](#).

**Table 2. Boot modes**

| Boot mode selection pins |       | Boot mode         | Aliasing                                        |
|--------------------------|-------|-------------------|-------------------------------------------------|
| BOOT1                    | BOOT0 |                   |                                                 |
| x                        | 0     | Main Flash memory | Main Flash memory is selected as the boot space |
| 0                        | 1     | System memory     | System memory is selected as the boot space     |
| 1                        | 1     | Embedded SRAM     | Embedded SRAM is selected as the boot space     |

The values on the BOOT pins are latched on the 4th rising edge of SYSCLK after a reset. It is up to the user to set the BOOT1 and BOOT0 pins after reset to select the required boot mode.

BOOT0 is a dedicated pin while BOOT1 is shared with a GPIO pin. Once BOOT1 has been sampled, the corresponding GPIO pin is free and can be used for other purposes.

The BOOT pins are also resampled when the device exits the Standby mode. Consequently, they must be kept in the required Boot mode configuration when the device is in the Standby mode. After this startup delay is over, the CPU fetches the top-of-stack value from address 0x0000 0000, then starts code execution from the boot memory starting from 0x0000 0004.

*Note: When the device boots from SRAM, in the application initialization code, you have to relocate the vector table in SRAM using the NVIC exception table and the offset register.*

In STM32F42xxx and STM32F43xxx devices, when booting from the main Flash memory, the application software can either boot from bank 1 or from bank 2. By default, boot from bank 1 is selected.

To select boot from Flash memory bank 2, set the BFB2 bit in the user option bytes. When this bit is set and the boot pins are in the boot from main Flash memory configuration, the device boots from system memory, and the boot loader jumps to execute the user application programmed in Flash memory bank 2. For further details, please refer to AN2606.

### Embedded bootloader

The embedded bootloader mode is used to reprogram the Flash memory using one of the following serial interfaces:

- USART1 (PA9/PA10)
- USART3 (PB10/11 and PC10/11)
- CAN2 (PB5/13)
- USB OTG FS (PA11/12) in Device mode (DFU: device firmware upgrade).

The USART peripherals operate at the internal 16 MHz oscillator (HSI) frequency, while the CAN and USB OTG FS require an external clock (HSE) multiple of 1 MHz (ranging from 4 to 26 MHz).

The embedded bootloader code is located in system memory. It is programmed by ST during production. For additional information, refer to application note AN2606.

### Physical remap in STM32F405xx/07xx and STM32F415xx/17xx

Once the boot pins are selected, the application software can modify the memory accessible in the code area (in this way the code can be executed through the ICode bus in place of the System bus). This modification is performed by programming the [Section 9.2.1: SYSCFG memory remap register \(SYSCFG\\_MEMRMP\)](#) in the SYSCFG controller.

The following memories can thus be remapped:

- Main Flash memory
- System memory
- Embedded SRAM1 (112 KB)
- FSMC bank 1 (NOR/PSRAM 1 and 2)

**Table 3. Memory mapping vs. Boot mode/physical remap  
in STM32F405xx/07xx and STM32F415xx/17xx**

| Addresses                                      | Boot/Remap in<br>main Flash memory | Boot/Remap in<br>embedded SRAM | Boot/Remap in<br>System memory   | Remap in FSMC                                  |
|------------------------------------------------|------------------------------------|--------------------------------|----------------------------------|------------------------------------------------|
| 0x2001 C000 - 0x2001 FFFF                      | SRAM2 (16 KB)                      | SRAM2 (16 KB)                  | SRAM2 (16 KB)                    | SRAM2 (16 KB)                                  |
| 0x2000 0000 - 0x2001 BFFF                      | SRAM1 (112 KB)                     | SRAM1 (112 KB)                 | SRAM1 (112 KB)                   | SRAM1 (112 KB)                                 |
| 0x1FFF 0000 - 0x1FFF 77FF                      | System memory                      | System memory                  | System memory                    | System memory                                  |
| 0x0810 0000 - 0x0FFF FFFF                      | Reserved                           | Reserved                       | Reserved                         | Reserved                                       |
| 0x0800 0000 - 0x080F FFFF                      | Flash memory                       | Flash memory                   | Flash memory                     | Flash memory                                   |
| 0x0400 0000 - 0x07FF FFFF                      | Reserved                           | Reserved                       | Reserved                         | FSMC bank 1<br>NOR/PSRAM 2<br>(128 MB Aliased) |
| 0x0000 0000 -<br>0x000F FFFF <sup>(1)(2)</sup> | Flash (1 MB) Aliased               | SRAM1 (112 KB)<br>Aliased      | System memory<br>(30 KB) Aliased | FSMC bank 1<br>NOR/PSRAM 1<br>(128 MB Aliased) |

1. When the FSMC is remapped at address 0x0000 0000, only the first two regions of bank 1 memory controller (bank 1 NOR/PSRAM 1 and NOR/PSRAM 2) can be remapped. In remap mode, the CPU can access the external memory via ICode bus instead of System bus which boosts up the performance.
2. Even when aliased in the boot memory space, the related memory is still accessible at its original memory space.

### Physical remap in STM32F42xxx and STM32F43xxx

Once the boot pins are selected, the application software can modify the memory accessible in the code area (in this way the code can be executed through the ICode bus in place of the System bus). This modification is performed by programming the [Section 9.2.1: SYSCFG memory remap register \(SYSCFG\\_MEMRMP\)](#) in the SYSCFG controller.

The following memories can thus be remapped:

- Main Flash memory
- System memory
- Embedded SRAM1 (112 KB)
- FMC bank 1 (NOR/PSRAM 1 and 2)
- FMC SDRAM bank 1

**Table 4. Memory mapping vs. Boot mode/physical remap  
in STM32F42xxx and STM32F43xxx**

| Addresses                 | Boot/Remap in<br>main Flash memory | Boot/Remap in<br>embedded SRAM | Boot/Remap in<br>System memory | Remap in FMC   |
|---------------------------|------------------------------------|--------------------------------|--------------------------------|----------------|
| 0x2002 0000 - 0x2002 FFFF | SRAM3 (64 KB)                      | SRAM3 (64 KB)                  | SRAM3 (64 KB)                  | SRAM3 (64 KB)  |
| 0x2001 C000 - 0x2001 FFFF | SRAM2 (16 KB)                      | SRAM2 (16 KB)                  | SRAM2 (16 KB)                  | SRAM2 (16 KB)  |
| 0x2000 0000 - 0x2001 BFFF | SRAM1 (112 KB)                     | SRAM1 (112 KB)                 | SRAM1 (112 KB)                 | SRAM1 (112 KB) |
| 0x1FFF 0000 - 0x1FFF 77FF | System memory                      | System memory                  | System memory                  | System memory  |
| 0x0810 0000 - 0x0FFF FFFF | Reserved                           | Reserved                       | Reserved                       | Reserved       |
| 0x0800 0000 - 0x081F FFFF | Flash memory                       | Flash memory                   | Flash memory                   | Flash memory   |

**Table 4. Memory mapping vs. Boot mode/physical remap  
in STM32F42xxx and STM32F43xxx (continued)**

| Addresses                                      | Boot/Remap in<br>main Flash memory | Boot/Remap in<br>embedded SRAM | Boot/Remap in<br>System memory   | Remap in FMC                                                                                |
|------------------------------------------------|------------------------------------|--------------------------------|----------------------------------|---------------------------------------------------------------------------------------------|
| 0x0400 0000 - 0x07FF FFFF                      | Reserved                           | Reserved                       | Reserved                         | FMC bank 1<br>NOR/PSRAM 2<br>(128 MB Aliased)                                               |
| 0x0000 0000 -<br>0x001F FFFF <sup>(1)(2)</sup> | Flash (2 MB) Aliased               | SRAM1 (112 KB)<br>Aliased      | System memory<br>(30 KB) Aliased | FMC bank 1<br>NOR/PSRAM 1<br>(128 MB Aliased)<br>or FMC SDRAM<br>bank 1 (128 MB<br>Aliased) |

1. When the FMC is remapped at address 0x0000 0000, only the first two regions of bank 1 memory controller (bank 1 NOR/PSRAM 1 and NOR/PSRAM 2) or SDRAM bank 1 can be remapped. In remap mode, the CPU can access the external memory via ICode bus instead of System bus which boosts up the performance.
2. Even when aliased in the boot memory space, the related memory is still accessible at its original memory space.

## 3 Embedded Flash memory interface

### 3.1 Introduction

The Flash memory interface manages CPU AHB I-Code and D-Code accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms.

The Flash memory interface accelerates code execution with a system of instruction prefetch and cache lines.

### 3.2 Main features

- Flash memory read operations
- Flash memory program/erase operations
- Read / write protections
- Prefetch on I-Code
- 64 cache lines of 128 bits on I-Code
- 8 cache lines of 128 bits on D-Code

*Figure 3* shows the Flash memory interface connection inside the system architecture.

**Figure 3. Flash memory interface connection inside system architecture  
(STM32F405xx/07xx and STM32F415xx/17xx)**

**Figure 4. Flash memory interface connection inside system architecture (STM32F42xxx and STM32F43xxx)**

### 3.3 Embedded Flash memory in STM32F405xx/07xx and STM32F415xx/17xx

The Flash memory has the following main features:

- Capacity up to 1 Mbyte
- 128 bits wide data read
- Byte, half-word, word and double word write
- Sector and mass erase
- Memory organization

The Flash memory is organized as follows:

- A main memory block divided into 4 sectors of 16 Kbytes, 1 sector of 64 Kbytes, and 7 sectors of 128 Kbytes
- System memory from which the device boots in System memory boot mode
- 512 OTP (one-time programmable) bytes for user data

The OTP area contains 16 additional bytes used to lock the corresponding OTP data block.

- Option bytes to configure read and write protection, BOR level, watchdog software/hardware and reset when the device is in Standby or Stop mode.
- Low-power modes (for details refer to the Power control (PWR) section of the reference manual)

Table 5. Flash module organization (STM32F40x and STM32F41x)

| Block         | Name      | Block base addresses      | Size       |
|---------------|-----------|---------------------------|------------|
| Main memory   | Sector 0  | 0x0800 0000 - 0x0800 3FFF | 16 Kbytes  |
|               | Sector 1  | 0x0800 4000 - 0x0800 7FFF | 16 Kbytes  |
|               | Sector 2  | 0x0800 8000 - 0x0800 BFFF | 16 Kbytes  |
|               | Sector 3  | 0x0800 C000 - 0x0800 FFFF | 16 Kbytes  |
|               | Sector 4  | 0x0801 0000 - 0x0801 FFFF | 64 Kbytes  |
|               | Sector 5  | 0x0802 0000 - 0x0803 FFFF | 128 Kbytes |
|               | Sector 6  | 0x0804 0000 - 0x0805 FFFF | 128 Kbytes |
|               | .         | .                         | .          |
|               | .         | .                         | .          |
|               | Sector 11 | 0x080E 0000 - 0x080F FFFF | 128 Kbytes |
| System memory |           | 0x1FFF 0000 - 0x1FFF 77FF | 30 Kbytes  |
| OTP area      |           | 0x1FFF 7800 - 0x1FFF 7A0F | 528 bytes  |
| Option bytes  |           | 0x1FFF C000 - 0x1FFF C00F | 16 bytes   |

### 3.4 Embedded Flash memory in STM32F42xxx and STM32F43xxx

The Flash memory has the following main features:

- Capacity up to 2 Mbyte with dual bank architecture supporting read-while-write capability (RWW)
- 128 bits wide data read
- Byte, half-word, word and double word write
- Sector, bank, and mass erase (both banks)
- Dual bank memory organization

The Flash memory is organized as follows:

- For each bank, a main memory block (1 Mbyte) divided into 4 sectors of 16 Kbytes, 1 sector of 64 Kbytes, and 7 sectors of 128 Kbytes
- System memory from which the device boots in System memory boot mode
- 512 OTP (one-time programmable) bytes for user data

The OTP area contains 16 additional bytes used to lock the corresponding OTP data block.

- Option bytes to configure read and write protection, BOR level, watchdog, dual bank boot mode, dual bank feature, software/hardware and reset when the device is in Standby or Stop mode.

- Dual bank organization on 1 Mbyte devices

The dual bank feature on 1 Mbyte devices is enabled by setting the DB1M option bit.

To obtain a dual bank Flash memory, the last 512 Kbytes of the single bank (sectors [8:11]) are re-structured in the same way as the first 512 Kbytes.

The sector numbering of dual bank memory organization is different from the single bank: the single bank memory contains 12 sectors whereas the dual bank memory contains 16 sectors (see [Table 7: 1 Mbyte Flash memory single bank vs dual bank organization \(STM32F42xxx and STM32F43xxx\)](#)).

For erase operation, the right sector numbering must be considered according the DB1M option bit.

- When the DB1M bit is reset, the erase operation must be performed on the default sector number.
- When the DB1M bit is set, to perform an erase operation on bank 2, the sector number must be programmed (sector number from 12 to 19). Refer to FLASH\_CR register for SNB (Sector number) configuration.

Refer to [Table 8: 1 Mbyte single bank Flash memory organization \(STM32F42xxx and STM32F43xxx\)](#) and [Table 9: 1 Mbyte dual bank Flash memory organization \(STM32F42xxx and STM32F43xxx\)](#) for details on 1 Mbyte single bank and 1 Mbyte dual bank organizations.

Table 6. Flash module - 2 Mbyte dual bank organization (STM32F42xxx and STM32F43xxx)

| Block        | Bank   | Name          | Block base addresses      | Size       |
|--------------|--------|---------------|---------------------------|------------|
| Main memory  | Bank 1 | Sector 0      | 0x0800 0000 - 0x0800 3FFF | 16 Kbytes  |
|              |        | Sector 1      | 0x0800 4000 - 0x0800 7FFF | 16 Kbytes  |
|              |        | Sector 2      | 0x0800 8000 - 0x0800 BFFF | 16 Kbytes  |
|              |        | Sector 3      | 0x0800 C000 - 0x0800 FFFF | 16 Kbyte   |
|              |        | Sector 4      | 0x0801 0000 - 0x0801 FFFF | 64 Kbytes  |
|              |        | Sector 5      | 0x0802 0000 - 0x0803 FFFF | 128 Kbytes |
|              |        | Sector 6      | 0x0804 0000 - 0x0805 FFFF | 128 Kbytes |
|              |        | -             | -                         | -          |
|              |        | -             | -                         | -          |
|              |        | -             | -                         | -          |
|              |        | Sector 11     | 0x080E 0000 - 0x080F FFFF | 128 Kbytes |
|              | Bank 2 | Sector 12     | 0x0810 0000 - 0x0810 3FFF | 16 Kbytes  |
|              |        | Sector 13     | 0x0810 4000 - 0x0810 7FFF | 16 Kbytes  |
|              |        | Sector 14     | 0x0810 8000 - 0x0810 BFFF | 16 Kbytes  |
|              |        | Sector 15     | 0x0810 C000 - 0x0810 FFFF | 16 Kbytes  |
|              |        | Sector 16     | 0x0811 0000 - 0x0811 FFFF | 64 Kbytes  |
|              |        | Sector 17     | 0x0812 0000 - 0x0813 FFFF | 128 Kbytes |
|              |        | Sector 18     | 0x0814 0000 - 0x0815 FFFF | 128 Kbytes |
|              |        |               | -                         | -          |
|              |        |               | -                         | -          |
|              |        |               | -                         | -          |
|              |        | Sector 23     | 0x081E 0000 - 0x081F FFFF | 128 Kbytes |
|              |        | System memory |                           |            |
| OTP          |        |               | 0x1FFF 7800 - 0x1FFF 7A0F | 528 bytes  |
| Option bytes | Bank 1 |               | 0x1FFF C000 - 0x1FFF C00F | 16 bytes   |

## 3.5 Read interface

### 3.5.1 Relation between CPU clock frequency and Flash memory read time

To correctly read data from Flash memory, the number of wait states (LATENCY) must be correctly programmed in the Flash access control register (FLASH\_ACR) according to the frequency of the CPU clock (HCLK) and the supply voltage of the device.

The prefetch buffer must be disabled when the supply voltage is below 2.1 V. The correspondence between wait states and CPU clock frequency is given in [Table 10](#) and [Table 11](#).

*Note:* On STM32F405xx/07xx and STM32F415xx/17xx devices:

- when VOS = '0', the maximum value of  $f_{HCLK}$  = 144 MHz.
- when VOS = '1', the maximum value of  $f_{HCLK}$  = 168 MHz.

On STM32F42xxx and STM32F43xxx devices:

- when VOS[1:0] = '0x01', the maximum value of  $f_{HCLK}$  is 120 MHz.
- when VOS[1:0] = '0x10', the maximum value of  $f_{HCLK}$  is 144 MHz. It can be extended to 168 MHz by activating the over-drive mode.
- when VOS[1:0] = '0x11', the maximum value of  $f_{HCLK}$  is 168 MHz. It can be extended to 180 MHz by activating the over-drive mode.
- The over-drive mode is not available when  $V_{DD}$  ranges from 1.8 to 2.1 V.

Refer to [Section 5.1.4: Voltage regulator for STM32F42xxx and STM32F43xxx](#) for details on how to activate the over-drive mode.

**Table 10. Number of wait states according to CPU clock (HCLK) frequency  
(STM32F405xx/07xx and STM32F415xx/17xx)**

| Wait states (WS)<br>(LATENCY) | HCLK (MHz)                     |                                |                                |                                                |

| 6 WS (7 CPU cycles)           |                                | $144 < \text{HCLK} \leq 168$   | $132 < \text{HCLK} \leq 154$   | $120 < \text{HCLK} \leq 140$                   |
| 7 WS (8 CPU cycles)           |                                | $168 < \text{HCLK} \leq 180$   | $154 < \text{HCLK} \leq 176$   | $140 < \text{HCLK} \leq 160$                   |
| 8 WS (9 CPU cycles)           |                                |                                | $176 < \text{HCLK} \leq 180$   | $160 < \text{HCLK} \leq 168$                   |

After reset, the CPU clock frequency is 16 MHz and 0 wait state (WS) is configured in the FLASH\_ACR register.

It is highly recommended to use the following software sequences to tune the number of wait states needed to access the Flash memory with the CPU frequency.

#### Increasing the CPU frequency

1. Program the new number of wait states to the LATENCY bits in the FLASH\_ACR register
2. Check that the new number of wait states is taken into account to access the Flash memory by reading the FLASH\_ACR register
3. Modify the CPU clock source by writing the SW bits in the RCC\_CFGR register
4. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC\_CFGR
5. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC\_CFGR register.

#### Decreasing the CPU frequency

1. Modify the CPU clock source by writing the SW bits in the RCC\_CFGR register
2. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC\_CFGR
3. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC\_CFGR register
4. Program the new number of wait states to the LATENCY bits in FLASH\_ACR
5. Check that the new number of wait states is used to access the Flash memory by reading the FLASH\_ACR register

*Note: A change in CPU clock configuration or wait state (WS) configuration may not be effective straight away. To make sure that the current CPU clock frequency is the one you have configured, you can check the AHB prescaler factor and clock source status values. To make sure that the number of WS you have programmed is effective, you can read the FLASH\_ACR register.*

### 3.5.2 Adaptive real-time memory accelerator (ART Accelerator™)

The proprietary Adaptive real-time (ART) memory accelerator is optimized for STM32 industry-standard Arm® Cortex®-M4 with FPU processors. It balances the inherent performance advantage of the Arm® Cortex®-M4 with FPU over Flash memory technologies, which normally requires the processor to wait for the Flash memory at higher operating frequencies.

To release the processor full performance, the accelerator implements an instruction prefetch queue and branch cache which increases program execution speed from the 128-bit Flash memory. Based on CoreMark benchmark, the performance achieved thanks to the ART accelerator is equivalent to 0 wait state program execution from Flash memory at a CPU frequency up to 180 MHz.

#### Instruction prefetch

Each Flash memory read operation provides 128 bits from either four instructions of 32 bits or 8 instructions of 16 bits according to the program launched. So, in case of sequential code, at least four CPU cycles are needed to execute the previous read instruction line. Prefetch on the I-Code bus can be used to read the next sequential instruction line from the Flash memory while the current instruction line is being requested by the CPU. Prefetch is enabled by setting the PRFTEN bit in the FLASH\_ACR register. This feature is useful if at least one wait state is needed to access the Flash memory.

*Figure 5* shows the execution of sequential 32-bit instructions with and without prefetch when 3 WSs are needed to access the Flash memory.

### Figure 5. Sequential 32-bit instruction execution

When the code is not sequential (branch), the instruction may not be present in the currently used instruction line or in the prefetched instruction line. In this case (miss), the penalty in terms of number of cycles is at least equal to the number of wait states.

### Instruction cache memory

To limit the time lost due to jumps, it is possible to retain 64 lines of 128 bits in an instruction cache memory. This feature can be enabled by setting the instruction cache enable (ICEN) bit in the FLASH\_ACR register. Each time a miss occurs (requested data not present in the currently used instruction line, in the prefetched instruction line or in the instruction cache memory), the line read is copied into the instruction cache memory. If some data contained in the instruction cache memory are requested by the CPU, they are provided without inserting any delay. Once all the instruction cache memory lines have been filled, the LRU (least recently used) policy is used to determine the line to replace in the instruction memory cache. This feature is particularly useful in case of code containing loops.

### Data management

Literal pools are fetched from Flash memory through the D-Code bus during the execution stage of the CPU pipeline. The CPU pipeline is consequently stalled until the requested literal pool is provided. To limit the time lost due to literal pools, accesses through the AHB databus D-Code have priority over accesses through the AHB instruction bus I-Code.

If some literal pools are frequently used, the data cache memory can be enabled by setting the data cache enable (DCEN) bit in the FLASH\_ACR register. This feature works like the instruction cache memory, but the retained data size is limited to 8 rows of 128 bits.

*Note:* Data in user configuration sector are not cacheable.

## 3.6 Erase and program operations

For any Flash memory program operation (erase or program), the CPU clock frequency (HCLK) must be at least 1 MHz. The contents of the Flash memory are not guaranteed if a device reset occurs during a Flash memory operation.

Any attempt to read the Flash memory on STM32F4xx while it is being written or erased, causes the bus to stall. Read operations are processed correctly once the program operation has completed. This means that code or data fetches cannot be performed while a write/erase operation is ongoing.

On STM32F42xxx and STM32F43xxx devices, two banks are available allowing read operation from one bank while a write/erase operation is performed to the other bank.

### 3.6.1 Unlocking the Flash control register

After reset, write is not allowed in the Flash control register (FLASH\_CR) to protect the Flash memory against possible unwanted operations due, for example, to electric disturbances. The following sequence is used to unlock this register:

1. Write KEY1 = 0x45670123 in the Flash key register (FLASH\_KEYR)
2. Write KEY2 = 0xCDEF89AB in the Flash key register (FLASH\_KEYR)

Any wrong sequence will return a bus error and lock up the FLASH\_CR register until the next reset.

The FLASH\_CR register can be locked again by software by setting the LOCK bit in the FLASH\_CR register.

**Note:** The FLASH\_CR register is not accessible in write mode when the BSY bit in the FLASH\_SR register is set. Any attempt to write to it with the BSY bit set will cause the AHB bus to stall until the BSY bit is cleared.

### 3.6.2 Program/erase parallelism

The Parallelism size is configured through the PSIZE field in the FLASH\_CR register. It represents the number of bytes to be programmed each time a write operation occurs to the Flash memory. PSIZE is limited by the supply voltage and by whether the external V<sub>PP</sub> supply is used or not. It must therefore be correctly configured in the FLASH\_CR register before any programming/erasing operation.

A Flash memory erase operation can only be performed by sector, bank or for the whole Flash memory (mass erase). The erase time depends on PSIZE programmed value. For more details on the erase time, refer to the electrical characteristics section of the device datasheet.

Table 12 provides the correct PSIZE values.

**Table 12. Program/erase parallelism**

|                  | Voltage range 2.7 - 3.6 V<br>with External V <sub>PP</sub> | Voltage range<br>2.7 - 3.6 V | Voltage range<br>2.4 - 2.7 V | Voltage range<br>2.1 - 2.4 V | Voltage range<br>1.8 V - 2.1 V |
|------------------|------------------------------------------------------------|------------------------------|------------------------------|------------------------------|--------------------------------|
| Parallelism size | x64                                                        | x32                          | x16                          |                              | x8                             |
| PSIZE(1:0)       | 11                                                         | 10                           | 01                           |                              | 00                             |

**Note:** Any program or erase operation started with inconsistent program parallelism/voltage range settings may lead to unpredicted results. Even if a subsequent read operation indicates that the logical value was effectively written to the memory, this value may not be retained.

To use V<sub>PP</sub>, an external high-voltage supply (between 8 and 9 V) must be applied to the V<sub>PP</sub> pad. The external supply must be able to sustain this voltage range even if the DC consumption exceeds 10 mA. It is advised to limit the use of V<sub>PP</sub> to initial programming on the factory line. The V<sub>PP</sub> supply must not be applied for more than an hour, otherwise the Flash memory might be damaged.

### 3.6.3 Erase

The Flash memory erase operation can be performed at sector level or on the whole Flash memory (Mass Erase). Mass Erase does not affect the OTP sector or the configuration sector.

#### Sector Erase

To erase a sector, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register
2. Set the SER bit and select the sector out of the 12 sectors (for STM32F405xx/07xx and STM32F415xx/17xx) and out of 24 (for STM32F42xxx and STM32F43xxx) in the main memory block you wish to erase (SNB) in the FLASH\_CR register
3. Set the STRT bit in the FLASH\_CR register
4. Wait for the BSY bit to be cleared

**Bank erase in STM32F42xxx and STM32F43xxx devices**

To erase bank 1 or bank 2, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register
2. Set MER or MER1 bit accordingly in the FLASH\_CR register
3. Set the STRT bit in the FLASH\_CR register
4. Wait for the BSY bit to be reset.

**Mass Erase**

To perform Mass Erase, the following sequence is recommended:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register
2. Set the MER bit in the FLASH\_CR register (on STM32F405xx/07xx and STM32F415xx/17xx devices)
3. Set both the MER and MER1 bits in the FLASH\_CR register (on STM32F42xxx and STM32F43xxx devices).
4. Set the STRT bit in the FLASH\_CR register
5. Wait for the BSY bit to be cleared

*Note: If MERx and SER bits are both set in the FLASH\_CR register, mass erase is performed. If both MERx and SER bits are reset and the STRT bit is set, an unpredictable behavior may occur without generating any error flag. This condition should be forbidden.*

**3.6.4 Programming****Standard programming**

The Flash memory programming sequence is as follows:

1. Check that no main Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register.
2. Set the PG bit in the FLASH\_CR register
3. Perform the data write operation(s) to the desired memory address (inside main memory block or OTP area):
  - Byte access in case of x8 parallelism
  - Half-word access in case of x16 parallelism
  - Word access in case of x32 parallelism
  - Double word access in case of x64 parallelism
4. Wait for the BSY bit to be cleared.

*Note: Successive write operations are possible without the need of an erase operation when changing bits from '1' to '0'. Writing '1' requires a Flash memory erase operation. If an erase and a program operation are requested simultaneously, the erase operation is performed first.*

### Programming errors

It is not allowed to program data to the Flash memory that would cross the 128-bit row boundary. In such a case, the write operation is not performed and a program alignment error flag (PGAERR) is set in the FLASH\_SR register.

The write access type (byte, half-word, word or double word) must correspond to the type of parallelism chosen (x8, x16, x32 or x64). If not, the write operation is not performed and a program parallelism error flag (PGPERR) is set in the FLASH\_SR register.

If the standard programming sequence is not respected (for example, if there is an attempt to write to a Flash memory address when the PG bit is not set), the operation is aborted and a program sequence error flag (PGSERR) is set in the FLASH\_SR register.

### Programming and caches

If a Flash memory write access concerns some data in the data cache, the Flash write access modifies the data in the Flash memory and the data in the cache.

If an erase operation in Flash memory also concerns data in the data or instruction cache, you have to make sure that these data are rewritten before they are accessed during code execution. If this cannot be done safely, it is recommended to flush the caches by setting the DCRST and ICRST bits in the FLASH\_CR register.

*Note:* The I/D cache should be flushed only when it is disabled (I/DCEN = 0).

### 3.6.5 Read-while-write (RWW)

In STM32F42xxx and STM32F43xxx devices, the Flash memory is divided into two banks allowing read-while-write operations. This feature allows to perform a read operation from one bank while an erase or program operation is performed to the other bank.

*Note:* Write-while-write operations are not allowed. As an example, it is not possible to perform an erase operation on one bank while programming the other one.

#### Read from bank 1 while erasing bank 2

While executing a program code from bank 1, it is possible to perform an erase operation on bank 2 (and vice versa). Follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register (BSY is active when erase/program operation is ongoing to bank 1 or bank 2)
2. Set MER or MER1 bit in the FLASH\_CR register
3. Set the STRT bit in the FLASH\_CR register
4. Wait for the BSY bit to be reset (or use the EOP interrupt).

#### Read from bank 1 while programming bank 2

While executing a program code (over the I-Code bus) from bank 1, it is possible to perform an program operation to the bank 2 (and vice versa). Follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register (BSY is active when erase/program operation is on going on bank 1 or bank 2)
2. Set the PG bit in the FLASH\_CR register
3. Perform the data write operation(s) to the desired memory address inside main memory block or OTP area
4. Wait for the BSY bit to be reset.

### 3.6.6 Interrupts

Setting the end of operation interrupt enable bit (EOPIE) in the FLASH\_CR register enables interrupt generation when an erase or program operation ends, that is when the busy bit (BSY) in the FLASH\_SR register is cleared (operation completed, correctly or not). In this case, the end of operation (EOP) bit in the FLASH\_SR register is set.

If an error occurs during a program, an erase, or a read operation request, one of the following error flags is set in the FLASH\_SR register:

- PGAERR, PGPERR, PGSERR (Program error flags)
- WRPERR (Protection error flag)
- RDERR (Read protection error flag) for STM32F42xxx and STM32F43xxx devices only.

In this case, if the error interrupt enable bit (ERRIE) is set in the FLASH\_CR register, an interrupt is generated and the operation error bit (OPERR) is set in the FLASH\_SR register.

*Note: If several successive errors are detected (for example, in case of DMA transfer to the Flash memory), the error flags cannot be cleared until the end of the successive write requests.*

**Table 13. Flash interrupt request**

| Interrupt event        | Event flag             | Enable control bit |
|------------------------|------------------------|--------------------|
| End of operation       | EOP                    | EOPIE              |
| Write protection error | WRPERR                 | ERRIE              |
| Programming error      | PGAERR, PGPERR, PGSERR | ERRIE              |
| Read protection error  | RDERR                  | ERRIE              |

## 3.7 Option bytes

### 3.7.1 Description of user option bytes

The option bytes are configured by the end user depending on the application requirements. [Table 14](#) shows the organization of these bytes inside the user configuration sector.

**Table 14. Option byte organization**

| Address     | [63:16]  | [15:0]                                                           |
|-------------|----------|------------------------------------------------------------------|
| 0x1FFF C000 | Reserved | ROP & user option bytes ( <b>RDP &amp; USER</b> )                |
| 0x1FFF C008 | Reserved | SPRMOD and Write protection <b>nWRP bits for sectors 0 to 11</b> |

Table 14. Option byte organization (continued)

| Address     | [63:16]  | [15:0]                                                            |
|-------------|----------|-------------------------------------------------------------------|
| 0x1FFE C000 | Reserved | Reserved                                                          |
| 0x1FFE C008 | Reserved | SPRMOD and Write protection <b>nWRP bits for sectors 12 to 23</b> |

Table 15. Description of the option bytes (STM32F405xx/07xx and STM32F415xx/17xx)

| Option bytes (word, address 0x1FFF C000)                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>RDP: Read protection option byte.</b><br>The read protection is used to protect the software code stored in Flash memory.                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Bits 15:8                                                                                                                                                                                                                                                                                            | 0xAA: Level 0, no protection<br>0xCC: Level 2, chip protection (debug and boot from RAM features disabled)<br>Others: Level 1, read protection of memories (debug features limited)                                                                                                                                                                                                                                                                                                                                                                            |
| <b>USER: User option byte</b><br>This byte is used to configure the following features: <ul style="list-style-type: none"> <li>– Select the watchdog event: Hardware or software</li> <li>– Reset event when entering the Stop mode</li> <li>– Reset event when entering the Standby mode</li> </ul> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 16. Description of the option bytes  
(STM32F42xxx and STM32F43xxx) (continued)**

| Option bytes (word, address 0x1FFE C008)                                                                      |                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit 15:12                                                                                                     | 0xF: not used                                                                                                                                                                                                                                                   |
| <b>nWRP</b> : Flash memory write protection option bytes for bank 2. Sectors 12 to 23 can be write protected. |                                                                                                                                                                                                                                                                 |
| Bits 11: 0                                                                                                    | nWRPi:<br>If SPRMOD is reset (default value):<br>0: Write protection active on sector i.<br>1: Write protection not active on sector i.<br>If SPRMOD is set (active):<br>0: PCROP protection not active on sector i.<br>1: PCROP protection active on sector i. |

### 3.7.2 Programming user option bytes

To run any operation on this sector, the option lock bit (OPTLOCK) in the Flash option control register (FLASH\_OPTCR) must be cleared. To be allowed to clear this bit, you have to perform the following sequence:

1. Write OPTKEY1 = 0x0819 2A3B in the Flash option key register (FLASH\_OPTKEYR)
2. Write OPTKEY2 = 0x4C5D 6E7F in the Flash option key register (FLASH\_OPTKEYR)

The user option bytes can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

#### Modifying user option bytes on STM32F405xx/07xx and STM32F415xx/17xx

To modify the user option value, follow the sequence below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register
2. Write the desired option value in the FLASH\_OPTCR register.
3. Set the option start bit (OPTSTRT) in the FLASH\_OPTCR register
4. Wait for the BSY bit to be cleared.

*Note:* The value of an option is automatically modified by first erasing the user configuration sector and then programming all the option bytes with the values contained in the FLASH\_OPTCR register.

#### Modifying user option bytes on STM32F42xxx and STM32F43xxx

The user option bytes for bank 1 and bank 2 cannot be modified independently. They must be updated concurrently.

To modify the user option byte value, follow the sequence below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH\_SR register
2. Write the bank 2 option byte value in the FLASH\_OPTCR1 register
3. Write the bank 1 option byte value in the FLASH\_OPTCR register.
4. Set the option start bit (OPTSTRT) in the FLASH\_OPTCR register
5. Wait for the BSY bit to be cleared

*Note:* The value of an option byte is automatically modified by first erasing the user configuration sector (bank 1 and 2) and then programming all the option bytes with the values contained in the FLASH\_OPTCR and FLASH\_OPTCR1 registers.

### 3.7.3 Read protection (RDP)

The user area in the Flash memory can be protected against read operations by an entrusted code. Three read protection levels are defined:

- **Level 0: no read protection**  
When the read protection level is set to Level 0 by writing 0xAA into the read protection option byte (RDP), all read/write operations (if no write protection is set) from/to the Flash memory or the backup SRAM are possible in all boot configurations (Flash user boot, debug or boot from RAM).
- **Level 1: read protection enabled**  
It is the default read protection level after option byte erase. The read protection Level 1 is activated by writing any value (except for 0xAA and 0xCC used to set Level 0 and Level 2, respectively) into the RDP option byte. When the read protection Level 1 is set:
  - No access (read, erase, program) to Flash memory or backup SRAM can be performed while the debug feature is connected or while booting from RAM or system memory bootloader. A bus error is generated in case of read request.
  - When booting from Flash memory, accesses (read, erase, program) to Flash memory and backup SRAM from user code are allowed.

When Level 1 is active, programming the protection option byte (RDP) to Level 0 causes the Flash memory and the backup SRAM to be mass-erased. As a result the user code area is cleared before the read protection is removed. The mass erase only erases the user code area. The other option bytes including write protections remain unchanged from before the mass-erase operation. The OTP area is not affected by mass erase and remains unchanged. Mass erase is performed only when Level 1 is active and Level 0 requested. When the protection level is increased (0->1, 1->2, 0->2) there is no mass erase.

- **Level 2: debug/chip read protection disabled**  
The read protection Level 2 is activated by writing 0xCC to the RDP option byte. When the read protection Level 2 is set:
  - All protections provided by Level 1 are active.
  - Booting from RAM or system memory bootloader is no more allowed.
  - JTAG, SWV (single-wire viewer), ETM, and boundary scan are disabled.
  - User option bytes can no longer be changed.
  - When booting from Flash memory, accesses (read, erase and program) to Flash memory and backup SRAM from user code are allowed.

Memory read protection Level 2 is an irreversible operation. When Level 2 is activated, the level of protection cannot be decreased to Level 0 or Level 1.

*Note:* The JTAG port is permanently disabled when Level 2 is active (acting as a JTAG fuse). As a consequence, boundary scan cannot be performed. STMicroelectronics is not able to perform analysis on defective parts on which the Level 2 protection has been set.

Table 17. Access versus read protection level

| Memory area                       | Protection Level | Debug features, Boot from RAM or from System memory bootloader |       |                   | Bootling from Flash memory |       |       |
|-----------------------------------|------------------|----------------------------------------------------------------|-------|-------------------|----------------------------|-------|-------|
|                                   |                  | Read                                                           | Write | Erase             | Read                       | Write | Erase |
| Main Flash Memory and Backup SRAM | Level 1          | NO                                                             |       | NO <sup>(1)</sup> | YES                        |       |       |
|                                   | Level 2          | NO                                                             |       |                   | YES                        |       |       |
| Option Bytes                      | Level 1          | YES                                                            |       |                   | YES                        |       |       |
|                                   | Level 2          | NO                                                             |       |                   | NO                         |       |       |
| OTP                               | Level 1          | NO                                                             |       | NA                | YES                        |       | NA    |
|                                   | Level 2          | NO                                                             |       | NA                | YES                        |       | NA    |

1. The main Flash memory and backup SRAM are only erased when the RDP changes from level 1 to 0. The OTP area remains unchanged.

Figure 6 shows how to go from one RDP level to another.

Figure 6. RDP levels

### 3.7.4 Write protections

Up to 24 user sectors in Flash memory can be protected against unwanted write operations due to loss of program counter contexts. When the non-write protection nWRPi bit ( $0 \leq i \leq 11$ ) in the FLASH\_OPTCR or FLASH\_OPTCR1 registers is low, the corresponding

sector cannot be erased or programmed. Consequently, a mass erase cannot be performed if one of the sectors is write-protected.

If an erase/program operation to a write-protected part of the Flash memory is attempted (sector protected by write protection bit, OTP part locked or part of the Flash memory that can never be written like the ICP), the write protection error flag (WRPERR) is set in the FLASH\_SR register.

On STM32F42xxx and STM32F43xxx devices, when the PCROP mode is set, the active level of nWRP<sub>i</sub> is high, and the corresponding sector *i* is write protected when nWRP<sub>i</sub> is high. A PCROP sector is automatically write protected.

*Note: When the memory read protection level is selected (RDP level = 1), it is not possible to program or erase Flash memory sector *i* if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM, even if nWRP<sub>i</sub> = 1.*

### Write protection error flag

If an erase/program operation to a write protected area of the Flash memory is performed, the Write Protection Error flag (WRPERR) is set in the FLASH\_SR register.

If an erase operation is requested, the WRPERR bit is set when:

- Mass, bank, sector erase are configured (MER or MER/MER1 and SER = 1)
- A sector erase is requested and the Sector Number SNB field is not valid
- A mass erase is requested while at least one of the user sector is write protected by option bit (MER or MER/MER1 = 1 and nWRP<sub>i</sub> = 0 with  $0 \leq i \leq 11$  bits in the FLASH\_OPTCRx register)
- A sector erase is requested on a write protected sector. (SER = 1, SNB = *i* and nWRP<sub>i</sub> = 0 with  $0 \leq i \leq 11$  bits in the FLASH\_OPTCRx register)
- The Flash memory is readout protected and an intrusion is detected.

If a program operation is requested, the WRPERR bit is set when:

- A write operation is performed on system memory or on the reserved part of the user specific sector.
- A write operation is performed to the user configuration sector
- A write operation is performed on a sector write protected by option bit.
- A write operation is requested on an OTP area which is already locked
- The Flash memory is read protected and an intrusion is detected.

### 3.7.5 Proprietary code readout protection (PCROP)

The proprietary readout protection (PCROP) is available only on STM32F42xxx and STM32F43xxx devices.

Flash memory user sectors (0 to 23) can be protected against D-bus read accesses by using the proprietary readout protection (PCROP).

The PCROP protection is selected as follows, through the SPRMOD option bit in the FLASH\_OPTCR register:

- SPRMOD = 0: nWRP<sub>i</sub> control the write protection of respective user sectors
- SPRMOD = 1: nWRP<sub>i</sub> control the read and write protection (PCROP) of respective user sectors.

When a sector is readout protected (PCROP mode activated), it can only be accessed for code fetch through ICODE Bus on Flash interface:

- Any read access performed through the D-bus triggers a RDERR flag error.
- Any program/erase operation on a PCROPed sector triggers a WRPERR flag error.

**Figure 7. PCROP levels**

The deactivation of the SPRMOD and/or the unprotection of PCROPed user sectors can only occur when, at the same time, the RDP level changes from 1 to 0. If this condition is not respected, the user option byte modification is cancelled and the write error WRPERR flag is set. The modification of the users option bytes (BOR\_LEV, RST\_STDBY, ..) is allowed since none of the active nWRP<sub>i</sub> bits is reset and SPRMOD is kept active.

**Note:** The active value of nWRP<sub>i</sub> bits is inverted when PCROP mode is active (SPRMOD = 1).  
If SPRMOD = 1 and nWRP<sub>i</sub> = 1, then user sector *i* of bank 1, respectively bank 2 is read/write protected (PCROP).

### 3.8 One-time programmable bytes

*Table 18* shows the organization of the one-time programmable (OTP) part of the OTP area.

**Table 18. OTP area organization**

| Block      | [128:96]               | [95:64]               | [63:32]              | [31:0]               | Address byte 0 |
|------------|------------------------|-----------------------|----------------------|----------------------|----------------|
| 0          | OTP0                   | OTP0                  | OTP0                 | OTP0                 | 0x1FFF 7800    |
|            | OTP0                   | OTP0                  | OTP0                 | OTP0                 | 0x1FFF 7810    |
| 1          | OTP1                   | OTP1                  | OTP1                 | OTP1                 | 0x1FFF 7820    |
|            | OTP1                   | OTP1                  | OTP1                 | OTP1                 | 0x1FFF 7830    |
| .          | .                      |                       |                      |                      | .              |
| .          | .                      |                       |                      |                      | .              |
| .          | .                      |                       |                      |                      | .              |
| 15         | OTP15                  | OTP15                 | OTP15                | OTP15                | 0x1FFF 79E0    |
|            | OTP15                  | OTP15                 | OTP15                | OTP15                | 0x1FFF 79F0    |
| Lock block | LOCKB15 ...<br>LOCKB12 | LOCKB11 ...<br>LOCKB8 | LOCKB7 ...<br>LOCKB4 | LOCKB3 ...<br>LOCKB0 | 0x1FFF 7A00    |

The OTP area is divided into 16 OTP data blocks of 32 bytes and one lock OTP block of 16 bytes. The OTP data and lock blocks cannot be erased. The lock block contains 16 bytes LOCKBi ( $0 \leq i \leq 15$ ) to lock the corresponding OTP data block (blocks 0 to 15). Each OTP data block can be programmed until the value 0x00 is programmed in the corresponding OTP lock byte. The lock bytes must only contain 0x00 and 0xFF values, otherwise the OTP bytes might not be taken into account correctly.

## 3.9 Flash interface registers

### 3.9.1 Flash access control register (FLASH\_ACR) for STM32F405xx/07xx and STM32F415xx/17xx

The Flash access control register is used to enable/disable the acceleration features and control the Flash memory access time according to CPU frequency.

Address offset: 0x00

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|          |    |    |       |       |      |      |        |          |    |    |    |    |              |    |    |
|----------|----|----|-------|-------|------|------|--------|----------|----|----|----|----|--------------|----|----|
| 31       | 30 | 29 | 28    | 27    | 26   | 25   | 24     | 23       | 22 | 21 | 20 | 19 | 18           | 17 | 16 |
| Reserved |    |    |       |       |      |      |        |          |    |    |    |    |              |    |    |
| 15       | 14 | 13 | 12    | 11    | 10   | 9    | 8      | 7        | 6  | 5  | 4  | 3  | 2            | 1  | 0  |
| Reserved |    |    | DCRST | ICRST | DCEN | ICEN | PRFTEN | Reserved |    |    |    |    | LATENCY[2:0] |    |    |
|          |    |    | rw    | w     | rw   | rw   | rw     |          |    |    |    |    | rw           | rw | rw |

Bits 31:13 Reserved, must be kept cleared.

Bit 12 **DCRST**: Data cache reset

0: Data cache is not reset

1: Data cache is reset

This bit can be written only when the D cache is disabled.

Bit 11 **ICRST**: Instruction cache reset

0: Instruction cache is not reset

1: Instruction cache is reset

This bit can be written only when the I cache is disabled.

Bit 10 **DCEN**: Data cache enable

0: Data cache is disabled

1: Data cache is enabled

Bit 9 **ICEN**: Instruction cache enable

0: Instruction cache is disabled

1: Instruction cache is enabled

Bit 8 **PRFTEN**: Prefetch enable

0: Prefetch is disabled

1: Prefetch is enabled

Bits 7:3 Reserved, must be kept cleared.

Bits 2:0 **LATENCY[2:0]**: Latency

These bits represent the ratio of the CPU clock period to the Flash memory access time.

000: Zero wait state

001: One wait state

010: Two wait states

011: Three wait states

100: Four wait states

101: Five wait states

110: Six wait states

111: Seven wait states

### 3.9.2 Flash access control register (FLASH\_ACR) for STM32F42xxx and STM32F43xxx

The Flash access control register is used to enable/disable the acceleration features and control the Flash memory access time according to CPU frequency.

Address offset: 0x00

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|          |    |    |       |       |      |      |        |          |    |    |    |              |    |    |    |

1: Data cache is enabled

Bit 9 **ICEN**: Instruction cache enable

0: Instruction cache is disabled

1: Instruction cache is enabled

Bit 8 **PRFTEN**: Prefetch enable

0: Prefetch is disabled

1: Prefetch is enabled

Bits 7:4 Reserved, must be kept cleared.

Bits 3:0 **LATENCY[3:0]**: Latency

These bits represent the ratio of the CPU clock period to the Flash memory access time.

0000: Zero wait state

0001: One wait state

0010: Two wait states

...

1110: Fourteen wait states

1111: Fifteen wait states

### 3.9.3 Flash key register (FLASH\_KEYR)

The Flash key register is used to allow access to the Flash control register and so, to allow program and erase operations.

Address offset: 0x04

Reset value: 0x0000 0000

Access: no wait state, word access

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| KEY[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w          | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| KEY[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w          | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |

Bits 31:0 **FKEYR[31:0]**: FPEC key

The following values must be programmed consecutively to unlock the FLASH\_CR register and allow programming/erasing it:

- a) KEY1 = 0x45670123
- b) KEY2 = 0xCDEF89AB

### 3.9.4 Flash option key register (FLASH\_OPTKEYR)

The Flash option key register is used to allow program and erase operations in the user configuration sector.

Address offset: 0x08

Reset value: 0x0000 0000

Access: no wait state, word access

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| OPTKEYR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w              | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| OPTKEYR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| w              | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  | w  |

Bits 31:0 **OPTKEYR[31:0]**: Option byte key

The following values must be programmed consecutively to unlock the FLASH\_OPTCR register and allow programming it:

- a) OPTKEY1 = 0x08192A3B
- b) OPTKEY2 = 0x4C5D6E7F

### 3.9.5 Flash status register (FLASH\_SR) for STM32F405xx/07xx and STM32F415xx/17xx

The Flash status register gives information on ongoing program and erase operations.

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|          |    |    |    |    |    |    |    |        |        |        |        |          |    |    |       |       |
|----------|----|----|----|----|----|----|----|--------|--------|--------|--------|----------|----|----|-------|-------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23     | 22     | 21     | 20     | 19       | 18 | 17 | 16    |       |
| Reserved |    |    |    |    |    |    |    |        |        |        |        |          |    |    | BSY   |       |
|          |    |    |    |    |    |    |    |        |        |        |        |          |    |    | r     |       |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7      | 6      | 5      | 4      | 3        | 2  | 1  | 0     |       |
| Reserved |    |    |    |    |    |    |    | PGSERR | PGPERR | PGAERR | WRPERR | Reserved |    |    | OPERR | EOP   |
|          |    |    |    |    |    |    |    | rc_w1  | rc_w1  | rc_w1  | rc_w1  |          |    |    | rc_w1 | rc_w1 |

Bits 31:17 Reserved, must be kept cleared.

Bit 16 **BSY**: Busy

This bit indicates that a Flash memory operation is in progress. It is set at the beginning of a Flash memory operation and cleared when the operation finishes or an error occurs.

0: no Flash memory operation ongoing

1: Flash memory operation ongoing

Bits 15:8 Reserved, must be kept cleared.

Bit 7 **PGSERR**: Programming sequence error

Set by hardware when a write access to the Flash memory is performed by the code while the control register has not been correctly configured.

Cleared by writing 1.

Bit 6 **PGPERR**: Programming parallelism error

Set by hardware when the size of the access (byte, half-word, word, double word) during the program sequence does not correspond to the parallelism configuration PSIZE (x8, x16, x32, x64).

Cleared by writing 1.

Bit 5 **PGAERR**: Programming alignment error

Set by hardware when the data to program cannot be contained in the same 128-bit Flash memory row.

Cleared by writing 1.

Bit 4 **WRPERR**: Write protection error

Set by hardware when an address to be erased/programmed belongs to a write-protected part of the Flash memory.

Cleared by writing 1.

Bits 3:2 Reserved, must be kept cleared.

Bit 1 **OPERR**: Operation error

Set by hardware when a flash operation (programming / erase /read) request is detected and can not be run because of parallelism, alignment, or write protection error. This bit is set only if error interrupts are enabled (ERRIE = 1).

Bit 0 **EOP**: End of operation

Set by hardware when one or more Flash memory operations (program/erase) has/have completed successfully. It is set only if the end of operation interrupts are enabled (EOPIE = 1). Cleared by writing a 1.

### 3.9.6 Flash status register (FLASH\_SR) for STM32F42xxx and STM32F43xxx

The Flash status register gives information on ongoing program and erase operations.

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|          |    |    |    |    |    |    |    |       |        |        |        |        |          |    |       |
|----------|----|----|----|----|----|----|----|-------|--------|--------|--------|--------|----------|----|-------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23    | 22     | 21     | 20     | 19     | 18       | 17 | 16    |
| Reserved |    |    |    |    |    |    |    |       |        |        |        |        |          |    | BSY   |
|          |    |    |    |    |    |    |    |       |        |        |        |        |          |    | r     |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7     | 6      | 5      | 4      | 3      | 2        | 1  | 0     |
| Reserved |    |    |    |    |    |    |    | RDERR | PGSERR | PGPERR | PGAERR | WRPERR | Reserved |    | OPERR |
|          |    |    |    |    |    |    |    | rc_w1 | rc_w1  | rc_w1  | rc_w1  | rc_w1  |          |    | rc_w1 |
|          |    |    |    |    |    |    |    |       |        |        |        |        |          |    | EOP   |
|          |    |    |    |    |    |    |    |       |        |        |        |        |          |    | rc_w1 |

Bits 31:17 Reserved, must be kept cleared.

Bit 16 **BSY**: Busy

This bit indicates that a Flash memory operation is in progress to/from one bank. It is set at the beginning of a Flash memory operation and cleared when the operation finishes or an error occurs.

0: no Flash memory operation ongoing

1: Flash memory operation ongoing

Bits 15:9 Reserved, must be kept cleared.

Bit 8 **RDERR**: Proprietary readout protection (PCROP) error

Set by hardware when a read access through the D-bus is performed to an address belonging to a proprietary readout protected Flash sector.

Cleared by writing 1.

Bit 7 **PGSERR**: Programming sequence error

Set by hardware when a write access to the Flash memory is performed by the code while the control register has not been correctly configured.

Cleared by writing 1.

Bit 6 **PGPERR**: Programming parallelism error

Set by hardware when the size of the access (byte, half-word, word, double word) during the program sequence does not correspond to the parallelism configuration PSIZE (x8, x16, x32, x64).

Cleared by writing 1.

Bit 5 **PGAERR**: Programming alignment error

Set by hardware when the data to program cannot be contained in the same 128-bit Flash memory row.

Cleared by writing 1.

Bit 4 **WRPERR**: Write protection error

Set by hardware when an address to be erased/programmed belongs to a write-protected part of the Flash memory.

Cleared by writing 1.

Bits 3:2 Reserved, must be kept cleared.

Bit 1 **OPERR**: Operation error

Set by hardware when a flash operation (programming/erase/read) request is detected and can not be run because of parallelism, alignment, write or read (PCROP) protection error. This bit is set only if error interrupts are enabled (ERRIE = 1).

Bit 0 **EOP**: End of operation

Set by hardware when one or more Flash memory operations (program/erase) has/have completed successfully. It is set only if the end of operation interrupts are enabled (EOPIE = 1).  
Cleared by writing a 1.

### 3.9.7 Flash control register (FLASH\_CR) for STM32F405xx/07xx and STM32F415xx/17xx

The Flash control register is used to configure and start Flash memory operations.

Address offset: 0x10

Reset value: 0x8000 0000

Access: no wait state when no Flash memory operation is ongoing, word, half-word and byte access.

|          |          |    |    |    |    |            |       |          |          |    |    |    |     |     |      |
|----------|----------|----|----|----|----|------------|-------|----------|----------|----|----|----|-----|-----|------|
| 31       | 30       | 29 | 28 | 27 | 26 | 25         | 24    | 23       | 22       | 21 | 20 | 19 | 18  | 17  | 16   |
| LOCK     | Reserved |    |    |    |    | ERRIE      | EOPIE | Reserved |          |    |    |    |     |     | STRT |
| rs       |          |    |    |    |    | rw         | rw    |          |          |    |    |    |     |     | rs   |
| 15       | 14       | 13 | 12 | 11 | 10 | 9          | 8     | 7        | 6        | 5  | 4  | 3  | 2   | 1   | 0    |
| Reserved |          |    |    |    |    | PSIZE[1:0] |       | Res.     | SNB[3:0] |    |    |    | MER | SER | PG   |
|          |          |    |    |    |    | rw         | rw    |          | rw       | rw | rw | rw | rw  | rw  | rw   |

- Bit 31 **LOCK**: Lock  
Write to 1 only. When it is set, this bit indicates that the FLASH\_CR register is locked. It is cleared by hardware after detecting the unlock sequence.  
In the event of an unsuccessful unlock operation, this bit remains set until the next reset.
- Bits 30:26 Reserved, must be kept cleared.
- Bit 25 **ERRIE**: Error interrupt enable  
This bit enables the interrupt generation when the OPERR bit in the FLASH\_SR register is set to 1.  
0: Error interrupt generation disabled  
1: Error interrupt generation enabled
- Bit 24 **EOPIE**: End of operation interrupt enable  
This bit enables the interrupt generation when the EOP bit in the FLASH\_SR register goes to 1.  
0: Interrupt generation disabled  
1: Interrupt generation enabled
- Bits 23:17 Reserved, must be kept cleared.
- Bit 16 **STRT**: Start  
This bit triggers an erase operation when set. It is set only by software and cleared when the BSY bit is cleared.
- Bits 15:10 Reserved, must be kept cleared.
- Bits 9:8 **PSIZE[1:0]**: Program size  
These bits select the program parallelism.  
00 program x8  
01 program x16  
10 program x32  
11 program x64
- Bit 7 Reserved, must be kept cleared.
- Bits 6:3 **SNB[3:0]**: Sector number  
These bits select the sector to erase.  
0000 sector 0  
0001 sector 1  
...  
1011 sector 11  
Others not allowed
- Bit 2 **MER**: Mass Erase  
Erase activated for all user sectors.
- Bit 1 **SER**: Sector Erase  
Sector Erase activated.
- Bit 0 **PG**: Programming  
Flash programming activated.

### 3.9.8 Flash control register (FLASH\_CR) for STM32F42xxx and STM32F43xxx

The Flash control register is used to configure and start Flash memory operations.

Address offset: 0x10

Reset value: 0x8000 0000

Access: no wait state when no Flash memory operation is ongoing, word, half-word and byte access.

|      |          |    |    |    |    |            |       |          |    |    |    |    |     |     |      |
|------|----------|----|----|----|----|------------|-------|----------|----|----|----|----|-----|-----|------|
| 31   | 30       | 29 | 28 | 27 | 26 | 25         | 24    | 23       | 22 | 21 | 20 | 19 | 18  | 17  | 16   |
| LOCK | Reserved |    |    |    |    | ERRIE      | EOPIE | Reserved |    |    |    |    |     |     | STRT |
| rs   |          |    |    |    |    | rw         | rw    |          |    |    |    |    |     |     | rs   |
| 15   | 14       | 13 | 12 | 11 | 10 | 9          | 8     | 7        | 6  | 5  | 4  | 3  | 2   | 1   | 0    |
| MER1 | Reserved |    |    |    |    | PSIZE[1:0] |       | SNB[4:0] |    |    |    |    | MER | SER | PG   |
| rw   |          |    |    |    |    | rw         | rw    | rw       | rw | rw | rw | rw | rw  | rw  | rw   |

Bit 31 **LOCK**: Lock

Write to 1 only. When it is set, this bit indicates that the FLASH\_CR register is locked. It is cleared by hardware after detecting the unlock sequence.

In the event of an unsuccessful unlock operation, this bit remains set until the next reset.

Bits 30:26 Reserved, must be kept cleared.

Bit 25 **ERRIE**: Error interrupt enable

This bit enables the interrupt generation when the OPERR bit in the FLASH\_SR register is set to 1.

0: Error interrupt generation disabled

1: Error interrupt generation enabled

Bit 24 **EOPIE**: End of operation interrupt enable

This bit enables the interrupt generation when the EOP bit in the FLASH\_SR register goes to 1.

0: Interrupt generation disabled

1: Interrupt generation enabled

Bits 23:17 Reserved, must be kept cleared.

Bit 16 **STRT**: Start

This bit triggers an erase operation when set. It is set only by software and cleared when the BSY bit is cleared.

Bit 15 **MER1**: Mass Erase of bank 2 sectors

Erase activated for bank 2 user sectors 12 to 23.

Bits 14:10 Reserved, must be kept cleared.

Bits 9:8 **PSIZE[1:0]**: Program size

These bits select the program parallelism.

00 program x8

01 program x16

10 program x32

11 program x64

Bits 7:3 **SNB[3:0]**: Sector number

These bits select the sector to erase.

0000: sector 0

0001: sector 1

...

01011: sector 11

01100: not allowed

01101: not allowed

01110: not allowed

01111: not allowed

10000: section 12

10001: section 13

...

11011 sector 23

11100: not allowed

11101: not allowed

11110: not allowed

11111: not allowed

Bit 2 **MER**: Mass Erase of bank 1 sectors

Erase activated of bank 1 sectors.

Bit 1 **SER**: Sector Erase

Sector Erase activated.

Bit 0 **PG**: Programming

Flash programming activated.

### 3.9.9 Flash option control register (FLASH\_OPTCR) for STM32F405xx/07xx and STM32F415xx/17xx

The FLASH\_OPTCR register is used to modify the user option bytes.

Address offset: 0x14

Reset value: 0x0FFF AAED. The option bits are loaded with values from Flash memory at reset release.

Access: no wait state when no Flash memory operation is ongoing, word, half-word and byte access.

|          |    |    |    |            |    |    |    |            |           |        |          |         |    |         |         |
|----------|----|----|----|------------|----|----|----|------------|-----------|--------|----------|---------|----|---------|---------|
| 31       | 30 | 29 | 28 | 27         | 26 | 25 | 24 | 23         | 22        | 21     | 20       | 19      | 18 | 17      | 16      |
| Reserved |    |    |    | nWRP[11:0] |    |    |    |            |           |        |          |         |    |         |         |
|          |    |    |    | rw         | rw | rw | rw | rw         | rw        | rw     | rw       | rw      | rw | rw      | rw      |
| 15       | 14 | 13 | 12 | 11         | 10 | 9  | 8  | 7          | 6         | 5      | 4        | 3       | 2  | 1       | 0       |
| RDP[7:0] |    |    |    |            |    |    |    | nRST_STDBY | nRST_STOP | WDG_SW | Reserved | BOR_LEV |    | OPTSTRT | OPTLOCK |
| rw       | rw | rw | rw | rw         | rw | rw | rw | rw         | rw        | rw     |          | rw      | rw | rs      | rs      |

Bits 31:28 Reserved, must be kept cleared.

Bits 27:16 **nWRP[11:0]**: Not write protect

These bits contain the value of the write-protection option bytes after reset. They can be written to program a new write protect value into Flash memory.

- 0: Write protection active on selected sector
- 1: Write protection inactive on selected sector

Bits 15:8 **RDP[7:0]**: Read protect

These bits contain the value of the read-protection option level after reset. They can be written to program a new read protection value into Flash memory.

- 0xAA: Level 0, read protection not active
- 0xCC: Level 2, chip read protection active
- Others: Level 1, read protection of memories active

Bits 7:5 **USER[2:0]**: User option bytes

These bits contain the value of the user option byte after reset. They can be written to program a new user option byte value into Flash memory.

- Bit 7: nRST\_STDBY
- Bit 6: nRST\_STOP
- Bit 5: WDG\_SW

*Note: When changing the WDG mode from hardware to software or from software to hardware, a system reset is required to make the change effective.*

Bit 4 Reserved, must be kept cleared. Always read as "0".

Bits 3:2 **BOR\_LEV[1:0]**: BOR reset Level

These bits contain the supply level threshold that activates/releases the reset. They can be written to program a new BOR level. By default, BOR is off. When the supply voltage ( $V_{DD}$ ) drops below the selected BOR level, a device reset is generated.

- 00: BOR Level 3 (VBOR3), brownout threshold level 3
- 01: BOR Level 2 (VBOR2), brownout threshold level 2
- 10: BOR Level 1 (VBOR1), brownout threshold level 1
- 11: BOR off, POR/PDR reset threshold level is applied

*Note: For full details about BOR characteristics, refer to the "Electrical characteristics" section in the device datasheet.*

Bit 1 **OPTSTR**: Option start

This bit triggers a user option operation when set. It is set only by software and cleared when the BSY bit is cleared.

Bit 0 **OPTLOCK**: Option lock

Write to 1 only. When this bit is set, it indicates that the FLASH\_OPTCR register is locked. This bit is cleared by hardware after detecting the unlock sequence.

In the event of an unsuccessful unlock operation, this bit remains set until the next reset.

### 3.9.10 Flash option control register (FLASH\_OPTCR) for STM32F42xxx and STM32F43xxx

The FLASH\_OPTCR register is used to modify the user option bytes.

Address offset: 0x14

Reset value: 0x0FFF AAED. The option bits are loaded with values from Flash memory at reset release.

Access: no wait state when no Flash memory operation is ongoing, word, half-word and byte access.

Bit 31 **SPRMOD**: Selection of protection mode for nWPRi bits

0: PCROP disabled. nWPRi bits used for Write protection on sector i.

1: PCROP enabled. nWPRi bits used for PCROP protection on sector i

Bit 30 **DB1M**: Dual-bank on 1 Mbyte Flash memory devices

0: 1 Mbyte single bank Flash memory (contiguous addresses in bank1)

1: 1 Mbyte dual bank Flash memory. The Flash memory is organized as two banks of 512 Kbytes each (see [Table 7: 1 Mbyte Flash memory single bank vs dual bank organization \(STM32F42xxx and STM32F43xxx\)](#) and [Table 9: 1 Mbyte dual bank Flash memory organization \(STM32F42xxx and STM32F43xxx\)](#)). To perform an erase operation, the right sector must be programmed (see [Table 7](#) for information on the sector numbering scheme).

*Note: If DB1M is set and an erase operation is performed on Bank 2 while the default sector number is selected (as an example, sector 8 is configured instead of sector 12), the erase operation on Bank 2 sector is not performed.*

Bits 29:28 Reserved, must be kept cleared.

Bits 27:16 **nWRP[11:0]**: Not write protect

These bits contain the value of the write-protection and read-protection (PCROP) option bytes for sectors 0 to 11 after reset. They can be written to program a new write-protect or PCROP value into Flash memory.

If SPRMOD is reset:

0: Write protection active on sector i

1: Write protection not active on sector i

If SPRMOD is set:

0: PCROP protection not active on sector i

1: PCROP protection active on sector i

Bits 15:8 **RDP[7:0]**: Read protect

These bits contain the value of the read-protection option level after reset. They can be written to program a new read protection value into Flash memory.

0xAA: Level 0, read protection not active

0xCC: Level 2, chip read protection active

Others: Level 1, read protection of memories active

**Bits 7:5 USER:** User option bytes

These bits contain the value of the user option byte after reset. They can be written to program a new user option byte value into Flash memory.

Bit 7: nRST\_STDBY

Bit 6: nRST\_STOP

Bit 5: WDG\_SW

*Note: When changing the WDG mode from hardware to software or from software to hardware, a system reset is required to make the change effective.*

**Bit 4 BFB2:** Dual-bank Boot option byte

0: Dual-bank boot disabled. Boot can be performed either from Flash memory bank 1 or from system memory depending on boot pin state (default)

1: Dual-bank boot enabled. Boot is always performed from system memory.

*Note: For STM32F42xx and STM32F43xx 1MB part numbers, this option bit must be kept cleared when DB1M=0.*

**Bits 3:2 BOR\_LEV:** BOR reset Level

These bits contain the supply level threshold that activates/releases the reset. They can be written to program a new BOR level. By default, BOR is off. When the supply voltage ( $V_{DD}$ ) drops below the selected BOR level, a device reset is generated.

00: BOR Level 3 (VBOR3), brownout threshold level 3

01: BOR Level 2 (VBOR2), brownout threshold level 2

10: BOR Level 1 (VBOR1), brownout threshold level 1

11: BOR off, POR/PDR reset threshold level is applied

*Note: For full details on BOR characteristics, refer to the "Electrical characteristics" section of the product datasheet.*

**Bit 1 OPTSTRT:** Option start

This bit triggers a user option operation when set. It is set only by software and cleared when the BSY bit is cleared.

**Bit 0 OPTLOCK:** Option lock

Write to 1 only. When this bit is set, it indicates that the FLASH\_OPTCR register is locked. This bit is cleared by hardware after detecting the unlock sequence.

In the event of an unsuccessful unlock operation, this bit remains set until the next reset.

### 3.9.11 Flash option control register (FLASH\_OPTCR1) for STM32F42xxx and STM32F43xxx

This register is available only on STM32F42xxx and STM32F43xxx.

The FLASH\_OPTCR1 register is used to modify the user option bytes for bank 2.

Address offset: 0x18

Reset value: 0x0FFF 0000. The option bits are loaded with values from Flash memory at reset release.

Access: no wait state when no Flash memory operation is ongoing, word, half-word and byte access.

|          |    |    |    |            |    |    |    |    |    |    |    |    |    |    |    |

| Reserved |    |    |    |            |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:28 Reserved, must be kept cleared.

Bits 27:16 **nWRP[11:0]**: Not write protect

These bits contain the value of the write-protection and read-protection (PCROP) option bytes for sectors 0 to 11 after reset. They can be written to program a new write-protect or PCROP value into Flash memory.

If SPRMOD is reset (default value):

0: Write protection active on sector i.

1: Write protection not active on sector i.

If SPRMOD is set:

0: PCROP protection not active on sector i.

1: PCROP protection active on sector i.

Bits 15:0 Reserved, must be kept cleared.

## 3.9.12 Flash interface register map

Table 19. Flash register map and reset values  
(STM32F405xx/07xx and STM32F415xx/17xx)

## 4 CRC calculation unit

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 4.1 CRC introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from a 32-bit data word and a fixed generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the EN/IEC 60335-1 standard, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link-time and stored at a given memory location.

### 4.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7  

$$- X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$
- Single input/output 32-bit data register
- CRC computation done in 4 AHB clock cycles (HCLK)
- General-purpose 8-bit register (can be used for temporary storage)

The block diagram is shown in [Figure 8](#).

**Figure 8. CRC calculation unit block diagram**

### 4.3 CRC functional description

The CRC calculation unit mainly consists of a single 32-bit data register, which:

- is used as an input register to enter new data in the CRC calculator (when writing into the register)
- holds the result of the previous CRC calculation (when reading the register)

Each write operation into the data register creates a combination of the previous CRC value and the new one (CRC computation is done on the whole 32-bit data word, and not byte per byte).

The write operation is stalled until the end of the CRC computation, thus allowing back-to-back write accesses or consecutive write and read accesses.

The CRC calculator can be reset to 0xFFFF FFFF with the RESET control bit in the CRC\_CR register. This operation does not affect the contents of the CRC\_IDR register.

### 4.4 CRC registers

The CRC calculation unit contains two data registers and a control register. The peripheral The CRC registers have to be accessed by words (32 bits).

#### 4.4.1 Data register (CRC\_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DR [31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DR [15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **Data register bits**

Used as an input register when writing new data into the CRC calculator.

Holds the previous CRC calculation result when it is read.

#### 4.4.2 Independent data register (CRC\_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    | IDR[7:0] |    |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    | rw       | rw | rw | rw | rw | rw | rw | rw |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **General-purpose 8-bit data register bits**

Can be used as a temporary storage location for one byte.

This register is not affected by CRC resets generated by the RESET bit in the CRC\_CR register.

### 4.4.3 Control register (CRC\_CR)

Address offset: 0x08

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17    | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1     | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    | RESET |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    | W     |    |

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **RESET bit**

Resets the CRC calculation unit and sets the data register to 0xFFFF FFFF.

This bit can only be set, it is automatically cleared by hardware.

### 4.4.4 CRC register map

The following table provides the CRC register map and reset values.

**Table 21. CRC calculation unit register map and reset values**

| Offset | Register    | 31-24         | 23-16 | 15-8 | 7                         | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|--------|-------------|---------------|-------|------|---------------------------|---|---|---|---|---|---|-------|
| 0x00   | CRC_DR      | Data register |       |      |                           |   |   |   |   |   |   |       |
|        | Reset value | 0xFFFF FFFF   |       |      |                           |   |   |   |   |   |   |       |
| 0x04   | CRC_IDR     | Reserved      |       |      | Independent data register |   |   |   |   |   |   |       |
|        | Reset value |               |       |      | 0x00                      |   |   |   |   |   |   |       |
| 0x08   | CRC_CR      | Reserved      |       |      |                           |   |   |   |   |   |   | RESET |
|        | Reset value |               |       |      |                           |   |   |   |   |   |   | 0     |

## 5 Power controller (PWR)

This section applies to the whole STM32F4xx family, unless otherwise specified.

## 5.1 Power supplies

The device requires a 1.8 to 3.6 V operating voltage supply ( $V_{DD}$ ). An embedded linear voltage regulator is used to supply the internal 1.2 V digital power.

The real-time clock (RTC), the RTC backup registers, and the backup SRAM (BKP SRAM) can be powered from the  $V_{\text{BAT}}$  voltage when the main  $V_{\text{DD}}$  supply is powered off.

**Note:** Depending on the operating power supply range, some peripheral may be used with limited functionality and performance. For more details refer to section “General operating conditions” in STM32F4xx datasheets.

**Figure 9. Power supply overview for STM32F405xx/07xx and STM32F415xx/17xx**

1.  $V_{DPA}$  and  $V_{SSA}$  must be connected to  $V_{DD}$  and  $V_{SS}$ , respectively.

Figure 10. Power supply overview for STM32F42xxx and STM32F43xxx

MS30482V2

1.  $V_{DDA}$  and  $V_{SSA}$  must be connected to  $V_{DD}$  and  $V_{SS}$ , respectively.

### 5.1.1 Independent A/D converter supply and reference voltage

To improve conversion accuracy, the ADC has an independent power supply which can be separately filtered and shielded from noise on the PCB.

- The ADC voltage supply input is available on a separate  $V_{DDA}$  pin.
- An isolated supply ground connection is provided on pin  $V_{SSA}$ .

To ensure a better accuracy of low voltage inputs, the user can connect a separate external reference voltage ADC input on  $V_{REF}$ . The voltage on  $V_{REF}$  ranges from 1.8 V to  $V_{DDA}$ .

### 5.1.2 Battery backup domain

#### Backup domain description

To retain the content of the RTC backup registers, backup SRAM, and supply the RTC when  $V_{DD}$  is turned off,  $V_{BAT}$  pin can be connected to an optional standby voltage supplied by a battery or by another source.

To allow the RTC to operate even when the main digital supply ( $V_{DD}$ ) is turned off, the  $V_{BAT}$  pin powers the following blocks:

- The RTC
- The LSE oscillator
- The backup SRAM when the low-power backup regulator is enabled
- PC13 to PC15 I/Os, plus PI8 I/O (when available)

The switch to the  $V_{BAT}$  supply is controlled by the power-down reset embedded in the Reset block.

---

**Warning:** During  $t_{RSTTEMPO}$  (temporization at  $V_{DD}$  startup) or after a PDR is detected, the power switch between  $V_{BAT}$  and  $V_{DD}$  remains connected to  $V_{BAT}$ .  
 During the startup phase, if  $V_{DD}$  is established in less than  $t_{RSTTEMPO}$  (Refer to the datasheet for the value of  $t_{RSTTEMPO}$ ) and  $V_{DD} > V_{BAT} + 0.6$  V, a current may be injected into  $V_{BAT}$  through an internal diode connected between  $V_{DD}$  and the power switch ( $V_{BAT}$ ).  
 If the power supply/battery connected to the  $V_{BAT}$  pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the  $V_{BAT}$  pin.

---

If no external battery is used in the application, it is recommended to connect the  $V_{BAT}$  pin to  $V_{DD}$  with a 100 nF external decoupling ceramic capacitor in parallel.

When the backup domain is supplied by  $V_{DD}$  (analog switch connected to  $V_{DD}$ ), the following functions are available:

- PC14 and PC15 can be used as either GPIO or LSE pins
- PC13 can be used as a GPIO as the RTC\_AF1 pin (refer to [Table 37: RTC\\_AF1 pin](#) for more details about this pin configuration)

**Note:** Due to the fact that the switch only sinks a limited amount of current (3 mA), the use of PI8 and PC13 to PC15 GPIOs in output mode is restricted: the speed has to be limited to 2 MHz with a maximum load of 30 pF and these I/Os must not be used as a current source (e.g. to drive an LED).

When the backup domain is supplied by  $V_{BAT}$  (analog switch connected to  $V_{BAT}$  because  $V_{DD}$  is not present), the following functions are available:

- PC14 and PC15 can be used as LSE pins only
- PC13 can be used as the RTC\_AF1 pin (refer to [Table 37: RTC\\_AF1 pin](#) for more details about this pin configuration)
- PI8 can be used as RTC\_AF2

### Backup domain access

After reset, the backup domain (RTC registers, RTC backup register and backup SRAM) is protected against possible unwanted write accesses. To enable access to the backup domain, proceed as follows:

- Access to the RTC and RTC backup registers
  1. Enable the power interface clock by setting the PWREN bits in the RCC\_APB1ENR register (see [Section 7.3.13](#) and [Section 6.3.13](#))
  2. Set the DBP bit in the [Section 5.4.1](#) and *PWR power control register (PWR\_CR) for STM32F42xxx and STM32F43xxx* to enable access to the backup domain
  3. Select the RTC clock source: see [Section 7.2.8: RTC/AWU clock](#)
  4. Enable the RTC clock by programming the RTCEN [15] bit in the [Section 7.3.20: RCC Backup domain control register \(RCC\\_BDCR\)](#)
- Access to the backup SRAM
  1. Enable the power interface clock by setting the PWREN bits in the RCC\_APB1ENR register (see [Section 7.3.13](#) and [Section 6.3.13](#) for STM32F405xx/07xx and STM32F415xx/17xx and STM32F42xxx and STM32F43xxx, respectively)
  2. Set the DBP bit in the *PWR power control register (PWR\_CR) for STM32F405xx/07xx and STM32F415xx/17xx* and *PWR power control register (PWR\_CR) for STM32F42xxx and STM32F43xxx* to enable access to the backup domain
  3. Enable the backup SRAM clock by setting BKPSRAMEN bit in the [RCC\\_AHB1 peripheral clock enable register \(RCC\\_AHB1ENR\)](#).

### RTC and RTC backup registers

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar, two programmable alarm interrupts, and a periodic programmable wakeup flag with interrupt capability. The RTC contains 20 backup data registers (80 bytes) which are reset when a tamper detection event occurs. For more details refer to [Section 26: Real-time clock \(RTC\)](#).

### Backup SRAM

The backup domain includes 4 Kbytes of backup SRAM addressed in 32-bit, 16-bit or 8-bit mode. Its content is retained even in Standby or  $V_{BAT}$  mode when the low-power backup regulator is enabled. It can be considered as an internal EEPROM when  $V_{BAT}$  is always present.

When the backup domain is supplied by  $V_{DD}$  (analog switch connected to  $V_{DD}$ ), the backup SRAM is powered from  $V_{DD}$  which replaces the  $V_{BAT}$  power supply to save battery life.

When the backup domain is supplied by  $V_{BAT}$  (analog switch connected to  $V_{BAT}$  because  $V_{DD}$  is not present), the backup SRAM is powered by a dedicated low-power regulator. This regulator can be ON or OFF depending whether the application needs the backup SRAM function in Standby and  $V_{BAT}$  modes or not. The power-down of this regulator is controlled

by a dedicated bit, the BRE control bit of the PWR\_CSR register (see [Section 5.4.2: PWR power control/status register \(PWR\\_CSR\) for STM32F405xx/07xx and STM32F415xx/17xx](#)).

The backup SRAM is not mass erased by a tamper event. When the Flash memory is read protected, the backup SRAM is also read protected to prevent confidential data, such as cryptographic private key, from being accessed. When the protection level change from level 1 to level 0 is requested, the backup SRAM content is erased.

Figure 11. Backup domain

### 5.1.3 Voltage regulator for STM32F405xx/07xx and STM32F415xx/17xx

An embedded linear voltage regulator supplies all the digital circuitries except for the backup domain and the Standby circuitry. The regulator output voltage is around 1.2 V.

This voltage regulator requires one or two external capacitors to be connected to one or two dedicated pins,  $V_{CAP\_1}$  and  $V_{CAP\_2}$  available in all packages. Specific pins must be connected either to  $V_{SS}$  or  $V_{DD}$  to activate or deactivate the voltage regulator. These pins depend on the package.

When activated by software, the voltage regulator is always enabled after Reset. It works in three different modes depending on the application modes.

- In **Run mode**, the regulator supplies full power to the 1.2 V domain (core, memories and digital peripherals). In this mode, the regulator output voltage (around 1.2 V) can be scaled by software to different voltage values:

Scale 1 or scale 2 can be configured on the fly through VOS (bit 15 of the PWR\_CR register).

The voltage scaling allows optimizing the power consumption when the device is clocked below the maximum system frequency.

- In **Standby mode**, the main regulator or the low-power regulator supplies to the 1.2 V domain, thus preserving the content of registers and internal SRAM. The voltage

regulator can be put either in main regulator mode (MR) or in low-power mode (LPR). The programmed voltage scale remains the same during Stop mode:

The programmed voltage scale remains the same during Stop mode (see [Section 5.4.1: PWR power control register \(PWR\\_CR\) for STM32F405xx/07xx and STM32F415xx/17xx](#)).

- In **Standby mode**, the regulator is powered down. The content of the registers and SRAM are lost except for the Standby circuitry and the backup domain.

*Note:* For more details, refer to the voltage regulator section in the STM32F405xx/07xx and STM32F415xx/17xx datasheets.

#### 5.1.4 Voltage regulator for STM32F42xxx and STM32F43xxx

An embedded linear voltage regulator supplies all the digital circuitries except for the backup domain and the Standby circuitry. The regulator output voltage is around 1.2 V.

This voltage regulator requires two external capacitors to be connected to two dedicated pins, V<sub>CAP\_1</sub> and V<sub>CAP\_2</sub> available in all packages. Specific pins must be connected either to V<sub>SS</sub> or V<sub>DD</sub> to activate or deactivate the voltage regulator. These pins depend on the package.

When activated by software, the voltage regulator is always enabled after Reset. It works in three different modes depending on the application modes (Run, Stop, or Standby mode).

- In **Run mode**, the main regulator supplies full power to the 1.2 V domain (core, memories and digital peripherals). In this mode, the regulator output voltage (around 1.2 V) can be scaled by software to different voltage values (scale 1, scale 2, and scale 3 can be configured through VOS[1:0] bits of the PWR\_CR register). The scale can be modified only when the PLL is OFF and the HSI or HSE clock source is selected as system clock source. The new value programmed is active only when the PLL is ON. When the PLL is OFF, the voltage scale 3 is automatically selected.

The voltage scaling allows optimizing the power consumption when the device is clocked below the maximum system frequency. After exit from Stop mode, the voltage

scale 3 is automatically selected. (see [Section 5.4.1: PWR power control register \(PWR\\_CR\) for STM32F405xx/07xx and STM32F415xx/17xx](#)).

2 operating modes are available:

- **Normal mode:** The CPU and core logic operate at maximum frequency at a given voltage scaling (scale 1, scale 2 or scale 3)
- **Over-drive mode:** This mode allows the CPU and the core logic to operate at a higher frequency than the normal mode for the voltage scaling scale 1 and scale 2.
- In **Stop mode:** the main regulator or low-power regulator supplies a low-power voltage to the 1.2V domain, thus preserving the content of registers and internal SRAM.  
The voltage regulator can be put either in main regulator mode (MR) or in low-power mode (LPR). Both modes can be configured by software as follows:
  - **Normal mode:** the 1.2 V domain is preserved in nominal leakage mode. It is the default mode when the main regulator (MR) or the low-power regulator (LPR) is enabled.
  - **Under-drive mode:** the 1.2 V domain is preserved in reduced leakage mode. This mode is only available with the main regulator or in low-power regulator mode (see [Table 22](#)).
- In **Standby mode:** the regulator is powered down. The content of the registers and SRAM are lost except for the Standby circuitry and the backup domain.

*Note:* Over-drive and under-drive mode are not available when the regulator is bypassed.  
For more details, refer to the voltage regulator section in the STM32F42xxx and STM32F43xxx datasheets.

**Table 22. Voltage regulator configuration mode versus device operating mode<sup>(1)</sup>**

| Voltage regulator configuration | Run mode | Sleep mode | Stop mode | Standby mode |
|---------------------------------|----------|------------|-----------|--------------|
| Normal mode                     | MR       | MR         | MR or LPR | -            |
| Over-drive mode <sup>(2)</sup>  | MR       | MR         | -         | -            |
| Under-drive mode                | -        | -          | MR or LPR | -            |
| Power-down mode                 | -        | -          | -         | Yes          |

1. '-' means that the corresponding configuration is not available.
2. The over-drive mode is not available when  $V_{DD} = 1.8$  to 2.1 V.

## Entering Over-drive mode

It is recommended to enter Over-drive mode when the application is not running critical tasks and when the system clock source is either HSI or HSE. To optimize the configuration time, enable the Over-drive mode during the PLL lock phase.

To enter Over-drive mode, follow the sequence below:

1. Select HSI or HSE as system clock.
2. Configure RCC\_PLLCFGR register and set PLLON bit of RCC\_CR register.
3. Set ODEN bit of PWR\_CR register to enable the Over-drive mode and wait for the ODRDY flag to be set in the PWR\_CSR register.
4. Set the ODSW bit in the PWR\_CR register to switch the voltage regulator from Normal mode to Over-drive mode. The System will be stalled during the switch but the PLL clock system will be still running during locking phase.
5. Wait for the ODSWRDY flag in the PWR\_CSR to be set.
6. Select the required Flash latency as well as AHB and APB prescalers.
7. Wait for PLL lock.
8. Switch the system clock to the PLL.
9. Enable the peripherals that are not generated by the System PLL (I2S clock, LCD-TFT clock, SAI1 clock, USB\_48MHz clock....).

**Note:** *The PLLI2S and PLLSAI can be configured at the same time as the system PLL.*

*During the Over-drive switch activation, no peripheral clocks should be enabled. The peripheral clocks must be enabled once the Over-drive mode is activated.*

*Entering Stop mode disables the Over-drive mode, as well as the PLL. The application software has to configure again the Over-drive mode and the PLL after exiting from Stop mode.*

## Exiting from Over-drive mode

It is recommended to exit from Over-drive mode when the application is not running critical tasks and when the system clock source is either HSI or HSE. There are two sequences that allow exiting from over-drive mode:

- By resetting simultaneously the ODEN and ODSW bits in the PWR\_CR register (sequence 1)
- By resetting first the ODSW bit to switch the voltage regulator to Normal mode and then resetting the ODEN bit to disable the Over-drive mode (sequence 2).

Example of sequence 1:

1. Select HSI or HSE as system clock source.
2. Disable the peripheral clocks that are not generated by the System PLL (I2S clock, LCD-TFT clock, SAI1 clock, USB\_48MHz clock,...)
3. Reset simultaneously the ODEN and the ODSW bits in the PWR\_CR register to switch back the voltage regulator to Normal mode and disable the Over-drive mode.
4. Wait for the ODWRDY flag of PWR\_CSR to be reset.

Example of sequence 2:

1. Select HSI or HSE as system clock source.
2. Disable the peripheral clocks that are not generated by the System PLL (I2S clock, LCD-TFT clock, SAI1 clock, USB\_48MHz clock,...).
3. Reset the ODSW bit in the PWR\_CR register to switch back the voltage regulator to Normal mode. The system clock is stalled during voltage switching.
4. Wait for the ODWRDY flag of PWR\_CSR to be reset.
5. Reset the ODEN bit in the PWR\_CR register to disable the Over-drive mode.

*Note: During step 3, the ODEN bit remains set and the Over-drive mode is still enabled but not active (ODSW bit is reset). If the ODEN bit is reset instead, the Over-drive mode is disabled and the voltage regulator is switched back to the initial voltage.*

## 5.2 Power supply supervisor

### 5.2.1 Power-on reset (POR)/power-down reset (PDR)

The device has an integrated POR/PDR circuitry that allows proper operation starting from 1.8 V.

The device remains in Reset mode when  $V_{DD}/V_{DDA}$  is below a specified threshold,  $V_{POR/PDR}$ , without the need for an external reset circuit. For more details concerning the power on/power-down reset threshold, refer to the electrical characteristics of the datasheet.

**Figure 12. Power-on reset/power-down reset waveform**

### 5.2.2 Brownout reset (BOR)

During power on, the Brownout reset (BOR) keeps the device under reset until the supply voltage reaches the specified  $V_{BOR}$  threshold.

$V_{BOR}$  is configured through device option bytes. By default, BOR is off. 3 programmable  $V_{BOR}$  threshold levels can be selected:

- BOR Level 3 (VBOR3). Brownout threshold level 3.
- BOR Level 2 (VBOR2). Brownout threshold level 2.
- BOR Level 1 (VBOR1). Brownout threshold level 1.

*Note:* For full details about BOR characteristics, refer to the "Electrical characteristics" section in the device datasheet.

When the supply voltage ( $V_{DD}$ ) drops below the selected  $V_{BOR}$  threshold, a device reset is generated.

The BOR can be disabled by programming the device option bytes. In this case, the power-on and power-down is then monitored by the POR/ PDR (see [Section 5.2.1: Power-on reset \(POR\)/power-down reset \(PDR\)](#)).

The BOR threshold hysteresis is ~100 mV (between the rising and the falling edge of the supply voltage).

Figure 13. BOR thresholds

### 5.2.3 Programmable voltage detector (PVD)

You can use the PVD to monitor the  $V_{DD}$  power supply by comparing it to a threshold selected by the PLS[2:0] bits in the [PWR power control register \(PWR\\_CR\)](#) for

*STM32F405xx/07xx and STM32F415xx/17xx and PWR power control register (PWR\_CR) for STM32F42xxx and STM32F43xxx.*

The PVD is enabled by setting the PVDE bit.

A PVDO flag is available, in the *PWR power control/status register (PWR\_CSR)* for *STM32F405xx/07xx and STM32F415xx/17xx*, to indicate if  $V_{DD}$  is higher or lower than the PVD threshold. This event is internally connected to the EXTI line16 and can generate an interrupt if enabled through the EXTI registers. The PVD output interrupt can be generated when  $V_{DD}$  drops below the PVD threshold and/or when  $V_{DD}$  rises above the PVD threshold depending on EXTI line16 rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.

**Figure 14. PVD thresholds**

## 5.3 Low-power modes

By default, the microcontroller is in Run mode after a system or a power-on reset. In Run mode the CPU is clocked by HCLK and the program code is executed. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The devices feature three low-power modes:

- Sleep mode (Cortex<sup>®</sup>-M4 with FPU core stopped, peripherals kept running)
- Stop mode (all clocks are stopped)
- Standby mode (1.2 V domain powered off)

In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks
- Gating the clocks to the APBx and AHBx peripherals when they are unused.

### Entering low-power mode

Low-power modes are entered by the MCU by executing the WFI (Wait For Interrupt), or WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M4 with FPU System Control register is set on Return from ISR.

Entering Low-power mode through WFI or WFE will be executed only if no interrupt is pending or no event is pending.

### Exiting low-power mode

The MCU exits from Sleep and Stop modes low-power mode depending on the way the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - NVIC IRQ interrupt:

When SEVONPEND = 0 in the Cortex®-M4 with FPU System Control register: by enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared. Only NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

When SEVONPEND = 1 in the Cortex®-M4 with FPU System Control register: by enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared. All NVIC interrupts will wakeup the MCU, even the disabled ones. Only enabled NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.
  - Event

This is done by configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It may be necessary to clear the interrupt flag in the peripheral.

The MCU exits from Standby low-power mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event occurs (see [Figure 237: RTC block diagram](#)).

After waking up from Standby mode, program execution restarts in the same way as after a Reset (boot pin sampling, option bytes loading, reset vector is fetched, etc.).

Only enabled NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

**Table 23. Low-power mode summary**

| Mode name                                 | Entry                                                            | Wakeup                                                                                                                                                  | Effect on 1.2 V domain clocks                                    | Effect on V <sub>DD</sub> domain clocks | Voltage regulator                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                           | WFE                                                              | Wakeup event                                                                                                                                            |                                                                  |                                         |                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Stop</b>                               | PDDS and LPDS bits + SLEEPDEEP bit + WFI, Return from ISR or WFE | Any EXTI line (configured in the EXTI registers, internal and external lines)                                                                           | All 1.2 V domain clocks OFF                                      | HSI and HSE oscillators OFF             | ON or in low-power mode (depends on <a href="#">PWR power control register (PWR_CR)</a> for <a href="#">STM32F405xx/07xx</a> and <a href="#">STM32F415xx/17xx</a> and <a href="#">PWR power control register (PWR_CR)</a> for <a href="#">STM32F405xx/07xx</a> and <a href="#">STM32F415xx/17xx</a> <a href="#">PWR power control register (PWR_CR)</a> for <a href="#">STM32F42xxx</a> and <a href="#">STM32F43xxx</a> ) |
| <b>Standby</b>                            | PDDS bit + SLEEPDEEP bit + WFI, Return from ISR or WFE           | WKUP pin rising edge, RTC alarm (Alarm A or Alarm B), RTC Wakeup event, RTC tamper events, RTC time stamp event, external reset in NRST pin, IWDG reset |                                                                  |                                         | OFF                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 5.3.1 Slowing down system clocks

In Run mode the speed of the system clocks (SYSCLK, HCLK, PCLK1, PCLK2) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down peripherals before entering Sleep mode.

For more details refer to [Section 7.3.3: RCC clock configuration register \(RCC\\_CFGR\)](#).

### 5.3.2 Peripheral clock gating

In Run mode, the HCLKx and PCLKx for individual peripherals and memories can be stopped at any time to reduce power consumption.

To further reduce power consumption in Sleep mode the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

Peripheral clock gating is controlled by the AHB1 peripheral clock enable register (RCC\_AHB1ENR), AHB2 peripheral clock enable register (RCC\_AHB2ENR), AHB3 peripheral clock enable register (RCC\_AHB3ENR) (see [Section 7.3.10: RCC AHB1 peripheral clock enable register \(RCC\\_AHB1ENR\)](#), [Section 7.3.11: RCC AHB2 peripheral clock enable register \(RCC\\_AHB2ENR\)](#), [Section 7.3.12: RCC AHB3 peripheral clock enable register \(RCC\\_AHB3ENR\)](#) for STM32F405xx/07xx and STM32F415xx/17xx, and [Section 6.3.10: RCC AHB1 peripheral clock register \(RCC\\_AHB1ENR\)](#), [Section 6.3.11: RCC AHB2 peripheral clock enable register \(RCC\\_AHB2ENR\)](#), and [Section 6.3.12: RCC AHB3 peripheral clock enable register \(RCC\\_AHB3ENR\)](#) for STM32F42xxx and STM32F43xxx).

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in RCC\_AHBxLPENR and RCC\_APBxLPENR registers.

### 5.3.3 Sleep mode

#### Entering Sleep mode

The Sleep mode is entered according to [Section : Entering low-power mode](#), when the SLEEPDEEP bit in the Cortex®-M4 with FPU System Control register is cleared.

Refer to [Table 24](#) and [Table 25](#) for details on how to enter Sleep mode.

*Note:* All interrupt pending bits must be cleared before the sleep mode entry.

#### Exiting Sleep mode

The Sleep mode is exited according to [Section : Exiting low-power mode](#).

Refer to [Table 24](#) and [Table 25](#) for more details on how to exit Sleep mode.

**Table 24. Sleep-now entry and exit**

| Sleep-now mode    | Description                                                                                                                                                                                                                                               |

| <b>Wakeup latency</b> | None                                                                                                                                                                                                                                                                               |

#### 5.3.4 Stop mode (STM32F405xx/07xx and STM32F415xx/17xx)

The Stop mode is based on the Cortex<sup>®</sup>-M4 with FPU deepsleep mode combined with peripheral clock gating. The voltage regulator can be configured either in normal or low-power mode. In Stop mode, all clocks in the 1.2 V domain are stopped, the PLLs, the HSI and the HSE RC oscillators are disabled. Internal SRAM and register contents are preserved.

By setting the FPDS bit in the PWR\_CR register, the Flash memory also enters power-down mode when the device enters Stop mode. When the Flash memory is in power-down mode, an additional startup delay is incurred when waking up from Stop mode (see [Table 26: Stop operating modes \(STM32F405xx/07xx and STM32F415xx/17xx\)](#) and [Section 5.4.1: PWR power control register \(PWR\\_CR\) for STM32F405xx/07xx and STM32F415xx/17xx](#)).

**Table 26. Stop operating modes  
(STM32F405xx/07xx and STM32F415xx/17xx)**

| Stop mode                   | LPDS bit | FPDS bit | Wake-up latency                                                                                            |
|-----------------------------|----------|----------|------------------------------------------------------------------------------------------------------------|
| STOP MR<br>(Main regulator) | 0        | 0        | HSI RC startup time                                                                                        |
| STOP MR-FPD                 | 0        | 1        | HSI RC startup time +<br>Flash wakeup time from Power Down<br>mode                                         |
| STOP LP                     | 1        | 0        | HSI RC startup time +<br>regulator wakeup time from LP mode                                                |
| STOP LP-FPD                 | 1        | 1        | HSI RC startup time +<br>Flash wakeup time from Power Down<br>mode +<br>regulator wakeup time from LP mode |

### Entering Stop mode (for STM32F405xx/07xx and STM32F415xx/17xx)

The Stop mode is entered according to [Section : Entering low-power mode](#), when the SLEEPDEEP bit in the Cortex<sup>®</sup>-M4 with FPU System Control register is set.

Refer to [Table 27](#) for details on how to enter the Stop mode.

To further reduce power consumption in Stop mode, the internal voltage regulator can be put in low-power mode. This is configured by the LPDS bit of the [PWR power control register \(PWR\\_CR\) for STM32F405xx/07xx and STM32F415xx/17xx](#) and [PWR power control register \(PWR\\_CR\) for STM32F42xxx and STM32F43xxx](#).

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, The Stop mode entry is delayed until the APB access is finished.

In Stop mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset. See [Section 21.3](#) in [Section 21: Independent watchdog \(IWDG\)](#).
- Real-time clock (RTC): this is configured by the RTCEN bit in the [Section 7.3.20: RCC Backup domain control register \(RCC\\_BDCR\)](#)
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the [Section 7.3.21: RCC clock control & status register \(RCC\\_CSR\)](#).
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the [Section 7.3.20: RCC Backup domain control register \(RCC\\_BDCR\)](#).

The ADC or DAC can also consume power during the Stop mode, unless they are disabled before entering it. To disable them, the ADON bit in the ADC\_CR2 register and the ENx bit in the DAC\_CR register must both be written to 0.

**Note:** *If the application needs to disable the external clock before entering Stop mode, the HSEON bit must first be disabled and the system clock switched to HSI.*

*Otherwise, if the HSEON bit is kept enabled while the external clock (external oscillator) can be removed before entering stop mode, the clock security system (CSS) feature must be enabled to detect any external oscillator failure and avoid a malfunction behavior when entering stop mode.*

### Exiting Stop mode (for STM32F405xx/07xx and STM32F415xx/17xx)

The Stop mode is exited according to [Section : Exiting low-power mode](#).

Refer to [Table 27](#) for more details on how to exit Stop mode.

When exiting Stop mode by issuing an interrupt or a wakeup event, the HSI RC oscillator is selected as system clock.

When the voltage regulator operates in low-power mode, an additional startup delay is incurred when waking up from Stop mode. By keeping the internal regulator ON during Stop mode, the consumption is higher although the startup time is reduced.

**Table 27. Stop mode entry and exit (for STM32F405xx/07xx and STM32F415xx/17xx)**

| Stop mode  | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 5.3.5 Stop mode (STM32F42xxx and STM32F43xxx)

The Stop mode is based on the Cortex<sup>®</sup>-M4 with FPU deepsleep mode combined with peripheral clock gating. The voltage regulator can be configured either in normal or low-power mode. In Stop mode, all clocks in the 1.2 V domain are stopped, the PLLs, the HSI and the HSE RC oscillators are disabled. Internal SRAM and register contents are preserved.

In Stop mode, the power consumption can be further reduced by using additional settings in the PWR\_CR register. However this will induce an additional startup delay when waking up from Stop mode (see [Table 28](#)).

Table 28. Stop operating modes (STM32F42xxx and STM32F43xxx)

| Voltage Regulator Mode |                          | UDEN[1:0]<br>bits | MRUDS<br>bit | LPUDS<br>bit | LPDS<br>bit | FPDS<br>bit | Wakeup latency                                                                                                                                     |

### Entering Stop mode (STM32F42xxx and STM32F43xxx)

The Stop mode is entered according to [Section : Entering low-power mode](#), when the SLEEPDEEP bit in the Cortex<sup>®</sup>-M4 with FPU System Control register is set.

Refer to [Table 29](#) for details on how to enter the Stop mode.

When the microcontroller enters in Stop mode, the voltage scale 3 is automatically selected. To further reduce power consumption in Stop mode, the internal voltage regulator can be put in low voltage mode. This is configured by the LPDS, MRUDS, LPUDS and UDEN bits of the [PWR power control register \(PWR\\_CR\) for STM32F405xx/07xx and STM32F415xx/17xx](#).

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, The Stop mode entry is delayed until the APB access is finished.

If the Over-drive mode was enabled before entering Stop mode, it is automatically disabled during when the Stop mode is activated.

In Stop mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset. See [Section 21.3](#) in [Section 21: Independent watchdog \(IWDG\)](#).
- Real-time clock (RTC): this is configured by the RTCEN bit in the [Section 7.3.20: RCC Backup domain control register \(RCC\\_BDCR\)](#)
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the [Section 7.3.21: RCC clock control & status register \(RCC\\_CSR\)](#).
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the [RCC Backup domain control register \(RCC\\_BDCR\)](#).

The ADC or DAC can also consume power during the Stop mode, unless they are disabled before entering it. To disable them, the ADON bit in the ADC\_CR2 register and the ENx bit in the DAC\_CR register must both be written to 0.

**Note:** *Before entering Stop mode, it is recommended to enable the clock security system (CSS) feature to prevent external oscillator (HSE) failure from impacting the internal MCU behavior.*

### Exiting Stop mode (STM32F42xxx and STM32F43xxx)

The Stop mode is exited according to [Section : Exiting low-power mode](#).

Refer to [Table 29](#) for more details on how to exit Stop mode.

When exiting Stop mode by issuing an interrupt or a wakeup event, the HSI RC oscillator is selected as system clock.

If the Under-drive mode was enabled, it is automatically disabled after exiting Stop mode.

When the voltage regulator operates in low voltage mode, an additional startup delay is incurred when waking up from Stop mode. By keeping the internal regulator ON during Stop mode, the consumption is higher although the startup time is reduced.

When the voltage regulator operates in Under-drive mode, an additional startup delay is induced when waking up from Stop mode.

Table 29. Stop mode entry and exit (STM32F42xxx and STM32F43xxx)

| Stop mode      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Wakeup latency | Refer to <a href="#">Table 28: Stop operating modes (STM32F42xxx and STM32F43xxx)</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 5.3.6 Standby mode

The Standby mode allows to achieve the lowest power consumption. It is based on the Cortex<sup>®</sup>-M4 with FPU deepsleep mode, with the voltage regulator disabled. The 1.2 V domain is consequently powered off. The PLLs, the HSI oscillator and the HSE oscillator are also switched off. SRAM and register contents are lost except for registers in the backup domain (RTC registers, RTC backup register and backup SRAM), and Standby circuitry (see [Figure 9](#)).

## Entering Standby mode

The Standby mode is entered according to [Section : Entering low-power mode](#), when the SLEEPDEEP bit in the Cortex®-M4 with FPU System Control register is set.

Refer to [Table 30](#) for more details on how to enter Standby mode.

In Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset. See [Section 21.3](#) in [Section 21: Independent watchdog \(IWDG\)](#).
- Real-time clock (RTC): this is configured by the RTCEN bit in the backup domain control register (RCC\_BDCR)
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the Control/status register (RCC\_CSR).
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the backup domain control register (RCC\_BDCR)

## Exiting Standby mode

The Standby mode is exited according to [Section : Exiting low-power mode](#). The SBF status flag in PWR\_CR (see [Section 5.4.2: PWR power control/status register \(PWR\\_CSR\) for STM32F405xx/07xx and STM32F415xx/17xx](#)) indicates that the MCU was in Standby mode. All registers are reset after wakeup from Standby except for PWR\_CR.

Refer to [Table 30](#) for more details on how to exit Standby mode.

**Table 30. Standby mode entry and exit**

| Standby mode   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mode entry     | WFI (Wait for Interrupt) or WFE (Wait for Event) while: <ul style="list-style-type: none"> <li>– SLEEPDEEP is set in Cortex®-M4 with FPU System Control register,</li> <li>– PDDS bit is set in Power Control register (PWR_CR),</li> <li>– No interrupt (for WFI) or event (for WFE) is pending,</li> <li>– WUF bit is cleared in Power Control register (PWR_CR),</li> <li>– the RTC flag corresponding to the chosen wakeup source (RTC Alarm A, RTC Alarm B, RTC wakeup, Tamper or Timestamp flags) is cleared</li> </ul> |

| Mode exit      | WKUP pin rising edge, RTC alarm (Alarm A and Alarm B), RTC wakeup, tamper event, time stamp event, external reset in NRST pin, IWDG reset.                                                                                                                                                                                                                                                                                                                                                                                    |
| Wakeup latency | Reset phase.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### I/O states in Standby mode

In Standby mode, all I/O pins are high impedance except for:

- Reset pad (still available)
- RTC\_AF1 pin (PC13) if configured for tamper, time stamp, RTC Alarm out, or RTC clock calibration out
- WKUP pin (PA0), if enabled

### Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop or Standby mode while the debug features are used. This is due to the fact that the Cortex®-M4 with FPU core is no longer clocked.

However, by setting some configuration bits in the DBGMCU\_CR register, the software can be debugged even when using the low-power modes extensively. For more details, refer to [Section 38.16.1: Debug support for low-power modes](#).

## 5.3.7 Programming the RTC alternate functions to wake up the device from the Stop and Standby modes

The MCU can be woken up from a low-power mode by an RTC alternate function.

The RTC alternate functions are the RTC alarms (Alarm A and Alarm B), RTC wakeup, RTC tamper event detection and RTC time stamp event detection.

These RTC alternate functions can wake up the system from the Stop and Standby low-power modes.

The system can also wake up from low-power modes without depending on an external interrupt (Auto-wakeup mode), by using the RTC alarm or the RTC wakeup events.

The RTC provides a programmable time base for waking up from the Stop or Standby mode at regular intervals.

For this purpose, two of the three alternate RTC clock sources can be selected by programming the RTCSEL[1:0] bits in the [Section 7.3.20: RCC Backup domain control register \(RCC\\_BDCR\)](#):

- Low-power 32.768 kHz external crystal oscillator (LSE OSC)  
This clock source provides a precise time base with a very low-power consumption (additional consumption of less than 1 µA under typical conditions)
- Low-power internal RC oscillator (LSI RC)  
This clock source has the advantage of saving the cost of the 32.768 kHz crystal. This internal RC oscillator is designed to use minimum power.

**RTC alternate functions to wake up the device from the Stop mode**

- To wake up the device from the Stop mode with an RTC alarm event, it is necessary to:
  - a) Configure the EXTI Line 17 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC Alarm Interrupt in the RTC\_CR register
  - c) Configure the RTC to generate the RTC alarm
- To wake up the device from the Stop mode with an RTC tamper or time stamp event, it is necessary to:
  - a) Configure the EXTI Line 21 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC time stamp Interrupt in the RTC\_CR register or the RTC tamper interrupt in the RTC\_TAFCR register
  - c) Configure the RTC to detect the tamper or time stamp event
- To wake up the device from the Stop mode with an RTC wakeup event, it is necessary to:
  - a) Configure the EXTI Line 22 to be sensitive to rising edges (Interrupt or Event modes)
  - b) Enable the RTC wakeup interrupt in the RTC\_CR register
  - c) Configure the RTC to generate the RTC Wakeup event

**RTC alternate functions to wake up the device from the Standby mode**

- To wake up the device from the Standby mode with an RTC alarm event, it is necessary to:
  - a) Enable the RTC alarm interrupt in the RTC\_CR register
  - b) Configure the RTC to generate the RTC alarm
- To wake up the device from the Standby mode with an RTC tamper or time stamp event, it is necessary to:
  - a) Enable the RTC time stamp interrupt in the RTC\_CR register or the RTC tamper interrupt in the RTC\_TAFCR register
  - b) Configure the RTC to detect the tamper or time stamp event
- To wake up the device from the Standby mode with an RTC wakeup event, it is necessary to:
  - a) Enable the RTC wakeup interrupt in the RTC\_CR register
  - b) Configure the RTC to generate the RTC wakeup event

**Safe RTC alternate function wakeup flag clearing sequence**

If the selected RTC alternate function is set before the PWR wakeup flag (WUTF) is cleared, it will not be detected on the next event as detection is made once on the rising edge.

To avoid bouncing on the pins onto which the RTC alternate functions are mapped, and exit correctly from the Stop and Standby modes, it is recommended to follow the sequence below before entering the Standby mode:

- When using RTC alarm to wake up the device from the low-power modes:
  - a) Disable the RTC alarm interrupt (ALRAIE or ALRBIE bits in the RTC\_CR register)
  - b) Clear the RTC alarm (ALRAF/ALRBF) flag

- c) Clear the PWR Wakeup (WUF) flag
- d) Enable the RTC alarm interrupt
- e) Re-enter the low-power mode
- When using RTC wakeup to wake up the device from the low-power modes:
  - a) Disable the RTC Wakeup interrupt (WUTIE bit in the RTC\_CR register)
  - b) Clear the RTC Wakeup (WUTF) flag
  - c) Clear the PWR Wakeup (WUF) flag
  - d) Enable the RTC Wakeup interrupt
  - e) Re-enter the low-power mode
- When using RTC tamper to wake up the device from the low-power modes:
  - a) Disable the RTC tamper interrupt (TAMPIE bit in the RTC\_TAFCR register)
  - b) Clear the Tamper (TAMP1F/TSF) flag
  - c) Clear the PWR Wakeup (WUF) flag
  - d) Enable the RTC tamper interrupt
  - e) Re-enter the low-power mode
- When using RTC time stamp to wake up the device from the low-power modes:
  - a) Disable the RTC time stamp interrupt (TSIE bit in RTC\_CR)
  - b) Clear the RTC time stamp (TSF) flag
  - c) Clear the PWR Wakeup (WUF) flag
  - d) Enable the RTC TimeStamp interrupt
  - e) Re-enter the low-power mode

## 5.4 Power control registers (STM32F405xx/07xx and STM32F415xx/17xx)

### 5.4.1 PWR power control register (PWR\_CR) for STM32F405xx/07xx and STM32F415xx/17xx

Address offset: 0x00

Reset value: 0x0000 4000 (reset by wakeup from Standby mode)

|          |     |          |    |    |    |      |     |          |    |    |      |      |      |      |      |
|----------|-----|----------|----|----|----|------|-----|----------|----|----|------|------|------|------|------|
| 31       | 30  | 29       | 28 | 27 | 26 | 25   | 24  | 23       | 22 | 21 | 20   | 19   | 18   | 17   | 16   |
| Reserved |     |          |    |    |    |      |     |          |    |    |      |      |      |      |      |
| 15       | 14  | 13       | 12 | 11 | 10 | 9    | 8   | 7        | 6  | 5  | 4    | 3    | 2    | 1    | 0    |
| Res.     | VOS | Reserved |    |    |    | FPDS | DBP | PLS[2:0] |    |    | PVDE | CSBF | CWUF | PDDS | LPDS |
|          | rw  |          |    |    |    | rw   | rw  | rw       | rw | rw | rw   | w    | w    | rw   | rw   |

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **VOS**: Regulator voltage scaling output selection

This bit controls the main internal voltage regulator output voltage to achieve a trade-off between performance and power consumption when the device does not operate at the maximum frequency.

0: Scale 2 mode

1: Scale 1 mode (default value at reset)

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **FPDS**: Flash power-down in Stop mode

When set, the Flash memory enters power-down mode when the device enters Stop mode. This allows to achieve a lower consumption in stop mode but a longer restart time.

0: Flash memory not in power-down when the device is in Stop mode

1: Flash memory in power-down when the device is in Stop mode

Bit 8 **DBP**: Disable backup domain write protection

In reset state, the RCC\_BDCR register, the RTC registers (including the backup registers), and the BRE bit of the PWR\_CSR register, are protected against parasitic write access. This bit must be set to enable write access to these registers.

0: Access to RTC and RTC Backup registers and backup SRAM disabled

1: Access to RTC and RTC Backup registers and backup SRAM enabled

Bits 7:5 **PLS[2:0]**: PVD level selection

These bits are written by software to select the voltage threshold detected by the Power Voltage Detector

000: 2.0 V

001: 2.1 V

010: 2.3 V

011: 2.5 V

100: 2.6 V

101: 2.7 V

110: 2.8 V

111: 2.9 V

*Note: Refer to the electrical characteristics of the datasheet for more details.*

- Bit 4 **PVDE**: Power voltage detector enable  
This bit is set and cleared by software.  
0: PVD disabled  
1: PVD enabled
- Bit 3 **CSBF**: Clear standby flag  
This bit is always read as 0.  
0: No effect  
1: Clear the SBF Standby Flag (write).
- Bit 2 **CWUF**: Clear wakeup flag  
This bit is always read as 0.  
0: No effect  
1: Clear the WUF Wakeup Flag **after 2 System clock cycles**
- Bit 1 **PDDS**: Power-down deepsleep  
This bit is set and cleared by software. It works together with the LPDS bit.  
0: Enter Stop mode when the CPU enters deepsleep. The regulator status depends on the LPDS bit.  
1: Enter Standby mode when the CPU enters deepsleep.
- Bit 0 **LPDS**: Low-power deepsleep  
This bit is set and cleared by software. It works together with the PDDS bit.  
0: Voltage regulator on during Stop mode  
1: Voltage regulator in low-power mode during Stop mode

#### 5.4.2 PWR power control/status register (PWR\_CSR) for STM32F405xx/07xx and STM32F415xx/17xx

Address offset: 0x04

Reset value: 0x0000 0000 (not reset by wakeup from Standby mode)

Additional APB cycles are needed to read this register versus a standard APB read.

|          |            |          |    |    |    |     |      |          |    |    |    |     |      |     |     |
|----------|------------|----------|----|----|----|-----|------|----------|----|----|----|-----|------|-----|-----|
| 31       | 30         | 29       | 28 | 27 | 26 | 25  | 24   | 23       | 22 | 21 | 20 | 19  | 18   | 17  | 16  |
| Reserved |            |          |    |    |    |     |      |          |    |    |    |     |      |     |     |
| 15       | 14         | 13       | 12 | 11 | 10 | 9   | 8    | 7        | 6  | 5  | 4  | 3   | 2    | 1   | 0   |
| Res      | VOS<br>RDY | Reserved |    |    |    | BRE | EWUP | Reserved |    |    |    | BRR | PVDO | SBF | WUF |
|          | r          |          |    |    |    | rw  | rw   |          |    |    |    | r   | r    | r   | r   |

Bits 31:15 Reserved, must be kept at reset value.

- Bit 14 **VOSRDY**: Regulator voltage scaling output selection ready bit  
0: Not ready  
1: Ready

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **BRE**: Backup regulator enable

When set, the Backup regulator (used to maintain backup SRAM content in Standby and  $V_{BAT}$  modes) is enabled. If BRE is reset, the backup regulator is switched off. The backup SRAM can still be used but its content will be lost in the Standby and  $V_{BAT}$  modes. Once set, the application must wait that the Backup Regulator Ready flag (BRR) is set to indicate that the data written into the RAM will be maintained in the Standby and  $V_{BAT}$  modes.

0: Backup regulator disabled

1: Backup regulator enabled

*Note: This bit is not reset when the device wakes up from Standby mode, by a system reset, or by a power reset.*

Bit 8 **EWUP**: Enable WKUP pin

This bit is set and cleared by software.

0: WKUP pin is used for general purpose I/O. An event on the WKUP pin does not wakeup the device from Standby mode.

1: WKUP pin is used for wakeup from Standby mode and forced in input pull down configuration (rising edge on WKUP pin wakes-up the system from Standby mode).

*Note: This bit is reset by a system reset.*

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **BRR**: Backup regulator ready

Set by hardware to indicate that the Backup Regulator is ready.

0: Backup Regulator not ready

1: Backup Regulator ready

*Note: This bit is not reset when the device wakes up from Standby mode or by a system reset or power reset.*

Bit 2 **PVDO**: PVD output

This bit is set and cleared by hardware. It is valid only if PVD is enabled by the PVDE bit.

0:  $V_{DD}$  is higher than the PVD threshold selected with the PLS[2:0] bits.

1:  $V_{DD}$  is lower than the PVD threshold selected with the PLS[2:0] bits.

*Note: The PVD is stopped by Standby mode. For this reason, this bit is equal to 0 after Standby or reset until the PVDE bit is set.*

Bit 1 **SBF**: Standby flag

This bit is set by hardware and cleared only by a POR/PDR (power-on reset/power-down reset) or by setting the CSBF bit in the PWR\_CR register.

0: Device has not been in Standby mode

1: Device has been in Standby mode

Bit 0 **WUF**: Wakeup flag

This bit is set by hardware and cleared either by a system reset or by setting the CWUF bit in the PWR\_CR register.

0: No wakeup event occurred

1: A wakeup event was received from the WKUP pin or from the RTC alarm (Alarm A or Alarm B), RTC Tamper event, RTC TimeStamp event or RTC Wakeup).

*Note: An additional wakeup event is detected if the WKUP pin is enabled (by setting the EWUP bit) when the WKUP pin level is already high.*

## 5.5 Power control registers (STM32F42xxx and STM32F43xxx)

### 5.5.1 PWR power control register (PWR\_CR) for STM32F42xxx and STM32F43xxx

Address offset: 0x00

Reset value: 0x0000 C000 (reset by wakeup from Standby mode)

|          |    |       |      |       |       |      |     |          |    |    |      |           |       |        |      |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 **UDEN[1:0]**: Under-drive enable in stop mode

These bits are set by software. They allow to achieve a lower power consumption in Stop mode but with a longer wakeup time.

When set, the digital area has less leakage consumption when the device enters Stop mode.

00: Under-drive disable

01: Reserved

10: Reserved

11: Under-drive enable

Bit 17 **ODSWEN**: Over-drive switching enabled.

This bit is set by software. It is cleared automatically by hardware after exiting from Stop mode or when the ODEN bit is reset. When set, It is used to switch to Over-drive mode.

To set or reset the ODSWEN bit, the HSI or HSE must be selected as system clock.

The ODSWEN bit must only be set when the ODRDY flag is set to switch to Over-drive mode.

0: Over-drive switching disabled

1: Over-drive switching enabled

*Note: On any over-drive switch (enabled or disabled), the system clock will be stalled during the internal voltage set up.*

Bit 16 **ODEN**: Over-drive enable

This bit is set by software. It is cleared automatically by hardware after exiting from Stop mode. It is used to enable the Over-drive mode in order to reach a higher frequency.

To set or reset the ODEN bit, the HSI or HSE must be selected as system clock. When the ODEN bit is set, the application must first wait for the Over-drive ready flag (ODRDY) to be set before setting the ODSWEN bit.

0: Over-drive disabled

1: Over-drive enabled

Bits 15:14 **VOS[1:0]**: Regulator voltage scaling output selection

These bits control the main internal voltage regulator output voltage to achieve a trade-off between performance and power consumption when the device does not operate at the maximum frequency (refer to the STM32F42xx and STM32F43xx datasheets for more details).

These bits can be modified only when the PLL is OFF. The new value programmed is active only when the PLL is ON. When the PLL is OFF, the voltage scale 3 is automatically selected.

00: Reserved (Scale 3 mode selected)

01: Scale 3 mode

10: Scale 2 mode

11: Scale 1 mode (reset value)

Bit 13 **ADCD1**:

0: No effect.

1: Refer to AN4073 for details on how to use this bit.

*Note: This bit can only be set when operating at supply voltage range 2.7 to 3.6V and when the Prefetch is OFF.*

Bit 12 Reserved, must be kept at reset value.

Bit 11 **MRUDS**: Main regulator in deepsleep under-drive mode

This bit is set and cleared by software.

0: Main regulator ON when the device is in Stop mode

1: Main Regulator in under-drive mode and Flash memory in power-down when the device is in Stop under-drive mode.

Bit 10 **LPUDS**: Low-power regulator in deepsleep under-drive mode

This bit is set and cleared by software.

0: Low-power regulator ON if LPDS bit is set when the device is in Stop mode

1: Low-power regulator in under-drive mode if LPDS bit is set and Flash memory in power-down when the device is in Stop under-drive mode.

Bit 9 **FPDS**: Flash power-down in Stop mode

When set, the Flash memory enters power-down mode when the device enters Stop mode.

This allows to achieve a lower consumption in stop mode but a longer restart time.

0: Flash memory not in power-down when the device is in Stop mode

1: Flash memory in power-down when the device is in Stop mode

Bit 8 **DBP**: Disable backup domain write protection

In reset state, the RCC\_BDCR register, the RTC registers (including the backup registers), and the BRE bit of the PWR\_CSR register, are protected against parasitic write access. This bit must be set to enable write access to these registers.

0: Access to RTC and RTC Backup registers and backup SRAM disabled

1: Access to RTC and RTC Backup registers and backup SRAM enabled

Bits 7:5 **PLS[2:0]**: PVD level selection

These bits are written by software to select the voltage threshold detected by the Power Voltage Detector

000: 2.0 V  
001: 2.1 V  
010: 2.3 V  
011: 2.5 V  
100: 2.6 V  
101: 2.7 V  
110: 2.8 V  
111: 2.9 V

*Note: Refer to the electrical characteristics of the datasheet for more details.*

Bit 4 **PVDE**: Power voltage detector enable

This bit is set and cleared by software.

0: PVD disabled  
1: PVD enabled

Bit 3 **CSBF**: Clear standby flag

This bit is always read as 0.

0: No effect  
1: Clear the SBF Standby Flag (write).

Bit 2 **CWUF**: Clear wakeup flag

This bit is always read as 0.

0: No effect  
1: Clear the WUF Wakeup Flag **after 2 System clock cycles**

Bit 1 **PDDS**: Power-down deepsleep

This bit is set and cleared by software. It works together with the LPDS bit.

0: Enter Stop mode when the CPU enters deepsleep. The regulator status depends on the LPDS bit.  
1: Enter Standby mode when the CPU enters deepsleep.

Bit 0 **LPDS**: Low-power deepsleep

This bit is set and cleared by software. It works together with the PDDS bit.

0: Main voltage regulator ON during Stop mode  
1: Low-power voltage regulator ON during Stop mode

### 5.5.2 PWR power control/status register (PWR\_CSR) for STM32F42xxx and STM32F43xxx

Address offset: 0x04

Reset value: 0x0000 0000 (not reset by wakeup from Standby mode)

Additional APB cycles are needed to read this register versus a standard APB read.

|          |        |          |    |    |    |    |     |      |           |    |    |            |       |         |       |     |
|----------|--------|----------|----|----|----|----|-----|------|-----------|----|----|------------|-------|---------|-------|-----|

| Res      | VOSRDY | Reserved |    |    |    |    | BRE | EWUP | Reserved. |    |    |            | BRR   | PVDO    | SBF   | WUF |
|          | r      |          |    |    |    |    | rw  | rw   |           |    |    |            | r     | r       | r     | r   |

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 **UDRDY[1:0]**: Under-drive ready flag

These bits are set by hardware when MCU entered stop Under-drive mode and exited. When the under-drive mode is enabled, these bits are not set as long as the MCU has not entered stop mode yet. They are cleared by programming them to 1.

00: Under-drive is disabled

01: Reserved

10: Reserved

11: Under-drive mode is activated in Stop mode.

Bit 17 **ODSWRDY**: Over-drive mode switching ready

0: Over-drive mode is not active.

1: Over-drive mode is active on digital area on 1.2 V domain

Bit 16 **ODRDY**: Over-drive mode ready

0: Over-drive mode not ready.

1: Over-drive mode ready

Bit 14 **VOSRDY**: Regulator voltage scaling output selection ready bit

0: Not ready

1: Ready

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **BRE**: Backup regulator enable

When set, the Backup regulator (used to maintain backup SRAM content in Standby and  $V_{BAT}$  modes) is enabled. If BRE is reset, the backup regulator is switched off. The backup SRAM can still be used but its content will be lost in the Standby and  $V_{BAT}$  modes. Once set, the application must wait that the Backup Regulator Ready flag (BRR) is set to indicate that the data written into the RAM will be maintained in the Standby and  $V_{BAT}$  modes.

0: Backup regulator disabled

1: Backup regulator enabled

*Note: This bit is not reset when the device wakes up from Standby mode, by a system reset, or by a power reset.*

Bit 8 **EWUP**: Enable WKUP pin

This bit is set and cleared by software.

0: WKUP pin is used for general purpose I/O. An event on the WKUP pin does not wakeup the device from Standby mode.

1: WKUP pin is used for wakeup from Standby mode and forced in input pull down configuration (rising edge on WKUP pin wakes-up the system from Standby mode).

*Note: This bit is reset by a system reset.*

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **BRR**: Backup regulator ready

Set by hardware to indicate that the Backup Regulator is ready.

0: Backup Regulator not ready

1: Backup Regulator ready

*Note: This bit is not reset when the device wakes up from Standby mode or by a system reset or power reset.*

Bit 2 **PVDO**: PVD output

This bit is set and cleared by hardware. It is valid only if PVD is enabled by the PVDE bit.

0:  $V_{DD}$  is higher than the PVD threshold selected with the PLS[2:0] bits.

1:  $V_{DD}$  is lower than the PVD threshold selected with the PLS[2:0] bits.

*Note: The PVD is stopped by Standby mode. For this reason, this bit is equal to 0 after Standby or reset until the PVDE bit is set.*

Bit 1 **SBF**: Standby flag

This bit is set by hardware and cleared only by a POR/PDR (power-on reset/power-down reset) or by setting the CSBF bit in the [PWR power control register \(PWR\\_CR\)](#) for [STM32F405xx/07xx and STM32F415xx/17xx](#)

0: Device has not been in Standby mode

1: Device has been in Standby mode

Bit 0 **WUF**: Wakeup flag

This bit is set by hardware and cleared either by a system reset or by setting the CWUF bit in the PWR\_CR register.

0: No wakeup event occurred

1: A wakeup event was received from the WKUP pin or from the RTC alarm (Alarm A or Alarm B), RTC Tamper event, RTC TimeStamp event or RTC Wakeup).

*Note: An additional wakeup event is detected if the WKUP pin is enabled (by setting the EWUP bit) when the WKUP pin level is already high.*

## 5.6 PWR register map

The following table summarizes the PWR registers.

**Table 31. PWR - register map and reset values for STM32F405xx/07xx and STM32F415xx/17xx**

| Offset | Register               | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15     | 14       | 13 | 12 | 11 | 10   | 9    | 8        | 7 | 6 | 5    | 4    | 3    | 2    | 1    | 0 |   |   |   |   |   |   |   |   |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 6 Reset and clock control for STM32F42xxx and STM32F43xxx (RCC)

### 6.1 Reset

There are three types of reset, defined as system Reset, power Reset and backup domain Reset.

#### 6.1.1 System reset

A system reset sets all registers to their reset values except the reset flags in the clock controller CSR register and the registers in the Backup domain (see [Figure 4](#)).

A system reset is generated when one of the following events occurs:

1. A low level on the NRST pin (external reset)
2. Window watchdog end of count condition (WWDG reset)
3. Independent watchdog end of count condition (IWDG reset)
4. A software reset (SW reset) (see [Software reset](#))
5. Low-power management reset (see [Low-power management reset](#))

##### Software reset

The reset source can be identified by checking the reset flags in the [RCC clock control & status register \(RCC\\_CSR\)](#).

The SYSRESETREQ bit in Cortex®-M4 with FPU Application Interrupt and Reset Control Register must be set to force a software reset on the device. Refer to the Cortex®-M4 with FPU technical reference manual for more details.

##### Low-power management reset

There are two ways of generating a low-power management reset:

1. Reset generated when entering the Standby mode:  
This type of reset is enabled by resetting the nRST\_STDBY bit in the user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering the Standby mode.
2. Reset when entering the Stop mode:  
This type of reset is enabled by resetting the nRST\_STOP bit in the user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering the Stop mode.

#### 6.1.2 Power reset

A power reset is generated when one of the following events occurs:

1. Power-on/power-down reset (POR/PDR reset) or brownout (BOR) reset
2. When exiting the Standby mode

A power reset sets all registers to their reset values except the Backup domain (see [Figure 4](#))

These sources act on the NRST pin and it is always kept low during the delay phase. The RESET service routine vector is fixed at address 0x0000\_0004 in the memory map.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20  $\mu$ s for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

**Figure 15. Simplified diagram of the reset circuit**

The Backup domain has two specific resets that affect only the Backup domain (see [Figure 4](#)).

### 6.1.3 Backup domain reset

The backup domain reset sets all RTC registers and the RCC\_BDCR register to their reset values. The BKPSRAM is not affected by this reset. The only way of resetting the BKPSRAM is through the Flash interface by requesting a protection level change from 1 to 0.

A backup domain reset is generated when one of the following events occurs:

1. Software reset, triggered by setting the BDRST bit in the [RCC Backup domain control register \(RCC\\_BDCR\)](#).
2.  $V_{DD}$  or  $V_{BAT}$  power on, if both supplies have previously been powered off.

## 6.2 Clocks

Three different clock sources can be used to drive the system clock (SYSCLK):

- HSI oscillator clock
- HSE oscillator clock
- Main PLL (PLL) clock

The devices have the two following secondary clock sources:

- 32 kHz low-speed internal RC (LSI RC) which drives the independent watchdog and, optionally, the RTC used for Auto-wakeup from the Stop/Standby mode.
- 32.768 kHz low-speed external crystal (LSE crystal) which optionally drives the RTC clock (RTCCLK)

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Figure 16. Clock tree

- For full details about the internal and external clock source characteristics, refer to the Electrical characteristics section in the device datasheet.
- When TIMPRE bit of the RCC\_DCKCFGR register is reset, if APBx prescaler is 1, then TIMxCLK = PCLKx, otherwise TIMxCLK = 2x PCLKx.
- When TIMPRE bit in the RCC\_DCKCFGR register is set, if APBx prescaler is 1,2 or 4, then TIMxCLK = HCLK, otherwise TIMxCLK = 4x PCLKx.

The clock controller provides a high degree of flexibility to the application in the choice of the external crystal or the oscillator to run the core and peripherals at the highest frequency and, guarantee the appropriate frequency for peripherals that need a specific clock like Ethernet, USB OTG FS and HS, I2S, SAI, LTDC, and SDIO.

Several prescalers are used to configure the AHB frequency, the high-speed APB (APB2) and the low-speed APB (APB1) domains. The maximum frequency of the AHB domain is 180 MHz. The maximum allowed frequency of the high-speed APB2 domain is 90 MHz. The maximum allowed frequency of the low-speed APB1 domain is 45 MHz.

All peripheral clocks are derived from the system clock (SYSCLK) except for:

- The USB OTG FS clock (48 MHz), the random analog generator (RNG) clock ( $\leq 48$  MHz) and the SDIO clock ( $\leq 48$  MHz) which are coming from a specific output of PLL (PLL48CLK)
- I2S clock  
To achieve high-quality audio performance, the I2S clock can be derived either from a specific PLL (PLLI2S) or from an external clock mapped on the I2S\_CKIN pin. For more information about I2S clock frequency and precision, refer to [Section 28.4.4: Clock generator](#).
- SAI1 clock  
The SAI1 clock is generated from a specific PLL (PLLSAI or PLLI2S) or from an external clock mapped on the I2S\_CKIN pin.  
The PLLSAI can be used as clock source for SAI1 peripheral in case the PLLI2S is programmed to achieve another audio sampling frequency (49.152 MHz or 11.2896 MHz), and the application requires both frequencies at the same time.
- LTDC clock  
The LTDC clock is generated from a specific PLL (PLLSAI).
- The USB OTG HS (60 MHz) clock which is provided from the external PHY
- The Ethernet MAC clocks (TX, RX and RMII) which are provided from the external PHY. For further information on the Ethernet configuration, please refer to [Section 33.4.4: MII/RMII selection](#) in the Ethernet peripheral description. When the Ethernet is used, the AHB clock frequency must be at least 25 MHz.

The RCC feeds the external clock of the Cortex System Timer (SysTick) with the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or with the Cortex clock (HCLK), configurable in the SysTick control and status register.

The timer clock frequencies for STM32F42xxx and STM32F43xxx are automatically set by hardware. There are two cases depending on the value of TIMPRE bit in RCC\_CFGR register:

- If TIMPRE bit in RCC\_DKCFGR register is reset:  
If the APB prescaler is configured to a division factor of 1, the timer clock frequencies (TIMxCLK) are set to PCLKx. Otherwise, the timer clock frequencies are twice the frequency of the APB domain to which the timers are connected:  $TIMxCLK = 2 \times PCLKx$ .
- If TIMPRE bit in RCC\_DKCFGR register is set:  
If the APB prescaler is configured to a division factor of 1, 2 or 4, the timer clock frequencies (TIMxCLK) are set to HCLK. Otherwise, the timer clock frequencies is four times the frequency of the APB domain to which the timers are connected:  $TIMxCLK = 4 \times PCLKx$ .

FCLK acts as Cortex<sup>®</sup>-M4 with FPU free-running clock. For more details, refer to the Cortex<sup>®</sup>-M4 with FPU technical reference manual.

### 6.2.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE external user clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

**Figure 17. HSE/ LSE clock sources**

#### External source (HSE bypass)

In this mode, an external clock source must be provided. You select this mode by setting the HSEBYP and HSEON bits in the [RCC clock control register \(RCC\\_CR\)](#). The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC\_IN pin while the OSC\_OUT pin should be left HI-Z. See [Figure 17](#).

#### External crystal/ceramic resonator (HSE crystal)

The HSE has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in [Figure 17](#). Refer to the electrical characteristics section of the *datasheet* for more details.

The HSERDY flag in the [RCC clock control register \(RCC\\_CR\)](#) indicates if the high-speed external oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the [RCC clock interrupt register \(RCC\\_CIR\)](#).

The HSE Crystal can be switched on and off using the HSEON bit in the [RCC clock control register \(RCC\\_CR\)](#).

### 6.2.2 HSI clock

The HSI clock signal is generated from an internal 16 MHz RC oscillator and can be used directly as a system clock, or used as PLL input.

The HSI RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator however, even with calibration the frequency is less accurate than an external crystal oscillator or ceramic resonator.

#### Calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1% accuracy at  $T_A = 25\text{ }^{\circ}\text{C}$ .

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the [RCC clock control register \(RCC\\_CR\)](#).

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. You can trim the HSI frequency in the application using the HSITRIM[4:0] bits in the [RCC clock control register \(RCC\\_CR\)](#).

The HSIRDY flag in the [RCC clock control register \(RCC\\_CR\)](#) indicates if the HSI RC is stable or not. At startup, the HSI RC output clock is not released until this bit is set by hardware.

The HSION bit can be switched on and off using the HSION bit in the [RCC clock control register \(RCC\\_CR\)](#).

The HSI signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to [Section 6.2.7: Clock security system \(CSS\) on page 157](#).

### 6.2.3 PLL configuration

The STM32F4xx devices feature three PLLs:

- A main PLL (PLL) clocked by the HSE or HSI oscillator and featuring two different output clocks:
  - The first output is used to generate the high speed system clock (up to 180 MHz)
  - The second output is used to generate the clock for the USB OTG FS (48 MHz), the random analog generator ( $\leq 48\text{ MHz}$ ) and the SDIO ( $\leq 48\text{ MHz}$ ).
- Two dedicated PLLs (PLLI2S and PLLSAI) used to generate an accurate clock to achieve high-quality audio performance on the I2S and SAI1 interfaces. PLLSAI is also used for the LCD-TFT clock.

Since the main-PLL configuration parameters cannot be changed once PLL is enabled, it is recommended to configure PLL before enabling it (selection of the HSI or HSE oscillator as PLL clock source, and configuration of division factors M, N, P, and Q).

The PLLI2S and PLLSAI use the same input clock as PLL (PLLM[5:0] and PLLSRC bits are common to both PLLs). However, the PLLI2S and PLLSAI have dedicated enable/disable and division factors (N and R) configuration bits. Once the PLLI2S and PLLSAI are enabled, the configuration parameters cannot be changed.

The three PLLs are disabled by hardware when entering Stop and Standby modes, or when an HSE failure occurs when HSE or PLL (clocked by HSE) are used as system clock. [RCC PLL configuration register \(RCC\\_PLLCFGR\)](#), [RCC clock configuration register \(RCC\\_CFGR\)](#), and [RCC Dedicated Clock Configuration Register \(RCC\\_DCKCFGR\)](#) can be used to configure PLL, PLLI2S, and PLLSAI.

## 6.2.4 LSE clock

The LSE clock is generated from a 32.768 kHz low-speed external crystal or ceramic resonator. It has the advantage providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE oscillator is switched on and off using the LSEON bit in [RCC Backup domain control register \(RCC\\_BDCR\)](#).

The LSERDY flag in the [RCC Backup domain control register \(RCC\\_BDCR\)](#) indicates if the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the [RCC clock interrupt register \(RCC\\_CIR\)](#).

### External source (LSE bypass)

In this mode, an external clock source must be provided. It must have a frequency up to 1 MHz. You select this mode by setting the LSEBYP and LSEON bits in the [RCC Backup domain control register \(RCC\\_BDCR\)](#). The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC32\_IN pin while the OSC32\_OUT pin should be left HI-Z. See [Figure 17](#).

## 6.2.5 LSI clock

The LSI RC acts as an low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG) and Auto-wakeup unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheets.

The LSI RC can be switched on and off using the LSION bit in the [RCC clock control & status register \(RCC\\_CSR\)](#).

The LSIRDY flag in the [RCC clock control & status register \(RCC\\_CSR\)](#) indicates if the low-speed internal oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the [RCC clock interrupt register \(RCC\\_CIR\)](#).

## 6.2.6 System clock (SYSCLK) selection

After a system reset, the HSI oscillator is selected as the system clock. When a clock source is used directly or through PLL as the system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready. Status bits in the [RCC clock control register \(RCC\\_CR\)](#) indicate which clock(s) is (are) ready and which clock is currently used as the system clock.

### 6.2.7 Clock security system (CSS)

The clock security system can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, this oscillator is automatically disabled, a clock failure event is sent to the break inputs of advanced-control timers TIM1 and TIM8, and an interrupt is generated to inform the software about the failure (clock security system interrupt CSSI), allowing the MCU to perform rescue operations. The CSSI is linked to the Cortex®-M4 with FPU NMI (non-maskable interrupt) exception vector.

*Note:* When the CSS is enabled, if the HSE clock happens to fail, the CSS generates an interrupt, which causes the automatic generation of an NMI. The NMI is executed indefinitely unless the CSS interrupt pending bit is cleared. As a consequence, the application has to clear the CSS interrupt in the NMI ISR by setting the CSSC bit in the Clock interrupt register (RCC\_CIR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly meaning that it is directly used as PLL input clock, and that PLL clock is the system clock) and a failure is detected, then the system clock switches to the HSI oscillator and the HSE oscillator is disabled.

If the HSE oscillator clock was the clock source of PLL used as the system clock when the failure occurred, PLL is also disabled. In this case, if the PLLI2S was enabled, it is also disabled when the HSE fails.

### 6.2.8 RTC/AWU clock

Once the RTCCLK clock source has been selected, the only possible way of modifying the selection is to reset the power domain.

The RTCCLK clock source can be either the HSE 1 MHz (HSE divided by a programmable prescaler), the LSE or the LSI clock. This is selected by programming the RTCSEL[1:0] bits in the [RCC Backup domain control register \(RCC\\_BDCR\)](#) and the RTCPRE[4:0] bits in [RCC clock configuration register \(RCC\\_CFGR\)](#). This selection cannot be modified without resetting the Backup domain.

If the LSE is selected as the RTC clock, the RTC operates normally if the backup or the system supply disappears. If the LSI is selected as the AWU clock, the AWU state is not guaranteed if the system supply disappears. If the HSE oscillator divided by a value between 2 and 31 is used as the RTC clock, the RTC state is not guaranteed if the backup or the system supply disappears.

The LSE clock is in the Backup domain, whereas the HSE and LSI clocks are not. As a consequence:

- If LSE is selected as the RTC clock:
  - The RTC continues to work even if the  $V_{DD}$  supply is switched off, provided the  $V_{BAT}$  supply is maintained.
- If LSI is selected as the Auto-wakeup unit (AWU) clock:
  - The AWU state is not guaranteed if the  $V_{DD}$  supply is powered off. Refer to [Section 6.2.5: LSI clock on page 156](#) for more details on LSI calibration.
- If the HSE clock is used as the RTC clock:
  - The RTC state is not guaranteed if the  $V_{DD}$  supply is powered off or if the internal voltage regulator is powered off (removing power from the 1.2 V domain).

*Note:* To read the RTC calendar register when the APB1 clock frequency is less than seven times the RTC clock frequency ( $f_{APB1} < 7 \times f_{RTCLK}$ ), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC\_TR gives the same result than the first one. Otherwise a third read access must be performed.

## 6.2.9 Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced ON and cannot be disabled. After the LSI oscillator temporization, the clock is provided to the IWDG.

## 6.2.10 Clock-out capability

Two microcontroller clock output (MCO) pins are available:

- MCO1  
You can output four different clock sources onto the MCO1 pin (PA8) using the configurable prescaler (from 1 to 5):
  - HSI clock
  - LSE clock
  - HSE clock
  - PLL clockThe desired clock source is selected using the MCO1PRE[2:0] and MCO1[1:0] bits in the [RCC clock configuration register \(RCC\\_CFGR\)](#).
- MCO2  
You can output four different clock sources onto the MCO2 pin (PC9) using the configurable prescaler (from 1 to 5):
  - HSE clock
  - PLL clock
  - System clock (SYSCLK)
  - PLLI2S clockThe desired clock source is selected using the MCO2PRE[2:0] and MCO2 bits in the [RCC clock configuration register \(RCC\\_CFGR\)](#).

For the different MCO pins, the corresponding GPIO port has to be programmed in alternate function mode.

The selected clock to output onto MCO must not exceed 100 MHz (the maximum I/O speed).

## 6.2.11 Internal/external clock measurement using TIM5/TIM11

It is possible to indirectly measure the frequencies of all on-board clock source generators by means of the input capture of TIM5 channel4 and TIM11 channel1 as shown in [Figure 18](#) and [Figure 19](#).

### Internal/external clock measurement using TIM5 channel4

TIM5 has an input multiplexer which allows choosing whether the input capture is triggered by the I/O or by an internal clock. This selection is performed through the TI4\_RMP [1:0] bits in the TIM5\_OR register.

The primary purpose of having the LSE connected to the channel4 input capture is to be able to precisely measure the HSI (this requires to have the HSI used as the system clock source). The number of HSI clock counts between consecutive edges of the LSE signal provides a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

The HSI oscillator has dedicated, user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio): the precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio, the better the measurement.

It is also possible to measure the LSI frequency: this is useful for applications that do not have a crystal. The ultralow-power LSI oscillator has a large manufacturing process deviation: by measuring it versus the HSI clock source, it is possible to determine its frequency with the precision of the HSI. The measured value can be used to have more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy.

Use the following procedure to measure the LSI frequency:

1. Enable the TIM5 timer and configure channel4 in Input capture mode.
2. This bit is set the TI4\_RMP bits in the TIM5\_OR register to 0x01 to connect the LSI clock internally to TIM5 channel4 input capture for calibration purposes.
3. Measure the LSI clock frequency using the TIM5 capture/compare 4 event or interrupt.
4. Use the measured LSI frequency to update the prescaler of the RTC depending on the desired time base and/or to compute the IWDG timeout.

**Figure 18. Frequency measurement with TIM5 in Input capture mode**

### Internal/external clock measurement using TIM11 channel1

TIM11 has an input multiplexer which allows choosing whether the input capture is triggered by the I/O or by an internal clock. This selection is performed through TI1\_RMP [1:0] bits in the TIM11\_OR register. The HSE\_RTC clock (HSE divided by a programmable prescaler) is connected to channel 1 input capture to have a rough indication of the external crystal frequency. This requires that the HSI is the system clock source. This can be useful for instance to ensure compliance with the IEC 60730/IEC 61335 standards which require to be able to determine harmonic or subharmonic frequencies (–50/+100% deviations).

Figure 19. Frequency measurement with TIM11 in Input capture mode

## 6.3 RCC registers

Refer to [Section 1.1: List of abbreviations for registers](#) for a list of abbreviations used in register descriptions.

### 6.3.1 RCC clock control register (RCC\_CR)

Address offset: 0x00

Reset value: 0x0000 XX83 where X is undefined.

Access: no wait state, word, half-word and byte access

|             |    |            |           |            |           |        |       |              |    |    |    |        |         |         |        |
|-------------|----|------------|-----------|------------|-----------|--------|-------|--------------|----|----|----|--------|---------|---------|--------|
| 31          | 30 | 29         | 28        | 27         | 26        | 25     | 24    | 23           | 22 | 21 | 20 | 19     | 18      | 17      | 16     |
| Reserved    |    | PLLSAI RDY | PLLSAI ON | PLLI2S RDY | PLLI2S ON | PLLRDY | PLLON | Reserved     |    |    |    | CSS ON | HSE BYP | HSE RDY | HSE ON |
|             |    | r          | rw        | r          | rw        | r      | rw    |              |    |    |    | rw     | rw      | r       | rw     |
| 15          | 14 | 13         | 12        | 11         | 10        | 9      | 8     | 7            | 6  | 5  | 4  | 3      | 2       | 1       | 0      |
| HSICAL[7:0] |    |            |           |            |           |        |       | HSITRIM[4:0] |    |    |    |        | Res.    | HSI RDY | HSION  |
| r           | r  | r          | r         | r          | r         | r      | r     | rw           | rw | rw | rw | rw     |         | r       | rw     |

Bits 31:28 Reserved, must be kept at reset value.

Bit 29 **PLLSAIRDY**: PLLSAI clock ready flag

Set by hardware to indicate that the PLLSAI is locked.

0: PLLSAI unlocked

1: PLLSAI locked

Bit 28 **PLLSAION**: PLLSAI enable

Set and cleared by software to enable PLLSAI.

Cleared by hardware when entering Stop or Standby mode.

0: PLLSAI OFF

1: PLLSAI ON

Bit 27 **PLLI2SRDY**: PLLI2S clock ready flag

Set by hardware to indicate that the PLLI2S is locked.

0: PLLI2S unlocked

1: PLLI2S locked

Bit 26 **PLLI2SON**: PLLI2S enable

Set and cleared by software to enable PLLI2S.

Cleared by hardware when entering Stop or Standby mode.

0: PLLI2S OFF

1: PLLI2S ON

Bit 25 **PLLRDY**: Main PLL (PLL) clock ready flag

Set by hardware to indicate that PLL is locked.

0: PLL unlocked

1: PLL locked

Bit 24 **PLLON**: Main PLL (PLL) enable

Set and cleared by software to enable PLL.

Cleared by hardware when entering Stop or Standby mode. This bit cannot be reset if PLL clock is used as the system clock.

0: PLL OFF

1: PLL ON

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CSSON**: Clock security system enable

Set and cleared by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if an oscillator failure is detected.

0: Clock security system OFF (Clock detector OFF)

1: Clock security system ON (Clock detector ON if HSE oscillator is stable, OFF if not)

Bit 18 **HSEBYP**: HSE clock bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit, to be used by the device.

The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE oscillator not bypassed

1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable. After the HSEON bit is cleared, HSERDY goes low after 6 HSE oscillator clock cycles.

0: HSE oscillator not ready

1: HSE oscillator ready

Bit 16 **HSEON**: HSE clock enable

Set and cleared by software.

Cleared by hardware to stop the HSE oscillator when entering Stop or Standby mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.

0: HSE oscillator OFF

1: HSE oscillator ON

Bits 15:8 **HSICAL[7:0]**: Internal high-speed clock calibration

These bits are initialized automatically at startup.

Bits 7:3 **HSITRIM[4:0]**: Internal high-speed clock trimming

These bits provide an additional user-programmable trimming value that is added to the HSICAL[7:0] bits. It can be programmed to adjust to variations in voltage and temperature that influence the frequency of the internal HSI RC.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HSIRDY**: Internal high-speed clock ready flag

Set by hardware to indicate that the HSI oscillator is stable. After the HSION bit is cleared, HSIRDY goes low after 6 HSI clock cycles.

0: HSI oscillator not ready

1: HSI oscillator ready

Bit 0 **HSION**: Internal high-speed clock enable

Set and cleared by software.

Set by hardware to force the HSI oscillator ON when leaving the Stop or Standby mode or in case of a failure of the HSE oscillator used directly or indirectly as the system clock. This bit cannot be cleared if the HSI is used directly or indirectly as the system clock.

0: HSI oscillator OFF

1: HSI oscillator ON

### 6.3.2 RCC PLL configuration register (RCC\_PLLCFGR)

Address offset: 0x04

Reset value: 0x2400 3010

Access: no wait state, word, half-word and byte access.

This register is used to configure the PLL clock outputs according to the formulas:

- $f_{(VCO \text{ clock})} = f_{(PLL \text{ clock input})} \times (PLL_N / PLL_M)$
- $f_{(PLL \text{ general clock output})} = f_{(VCO \text{ clock})} / PLL_P$
- $f_{(USB \text{ OTG FS, SDIO, RNG clock output})} = f_{(VCO \text{ clock})} / PLL_Q$

|          |       |    |    |       |       |       |       |          |        |          |       |       |       |       |       |
|----------|-------|----|----|-------|-------|-------|-------|----------|--------|----------|-------|-------|-------|-------|-------|
| 31       | 30    | 29 | 28 | 27    | 26    | 25    | 24    | 23       | 22     | 21       | 20    | 19    | 18    | 17    | 16    |
| Reserved |       |    |    | PLLQ3 | PLLQ2 | PLLQ1 | PLLQ0 | Reserved | PLLSRC | Reserved |       |       |       | PLLP1 | PLLP0 |
|          |       |    |    | rw    | rw    | rw    | rw    |          | rw     |          |       |       |       | rw    | rw    |
| 15       | 14    | 13 | 12 | 11    | 10    | 9     | 8     | 7        | 6      | 5        | 4     | 3     | 2     | 1     | 0     |
| Reserved | PLL_N |    |    |       |       |       |       |          |        | PLLM5    | PLLM4 | PLLM3 | PLLM2 | PLLM1 | PLLM0 |
|          | rw    | rw | rw | rw    | rw    | rw    | rw    | rw       | rw     | rw       | rw    | rw    | rw    | rw    | rw    |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **PLLQ**: Main PLL (PLL) division factor for USB OTG FS, SDIO and random number generator clocks

Set and cleared by software to control the frequency of USB OTG FS clock, the random number generator clock and the SDIO clock. These bits should be written only if PLL is disabled.

**Caution:** The USB OTG FS requires a 48 MHz clock to work correctly. The SDIO and the random number generator need a frequency lower than or equal to 48 MHz to work correctly.

USB OTG FS clock frequency = VCO frequency / PLLQ with  $2 \leq PLLQ \leq 15$

0000: PLLQ = 0, wrong configuration

0001: PLLQ = 1, wrong configuration

0010: PLLQ = 2

0011: PLLQ = 3

0100: PLLQ = 4

...

1111: PLLQ = 15

Bit 23 Reserved, must be kept at reset value.

Bit 22 **PLLSRC**: Main PLL(PLL) and audio PLL (PLLI2S) entry clock source

Set and cleared by software to select PLL and PLLI2S clock source. This bit can be written only when PLL and PLLI2S are disabled.

0: HSI clock selected as PLL and PLLI2S clock entry

1: HSE oscillator clock selected as PLL and PLLI2S clock entry

Bits 21:18 Reserved, must be kept at reset value.

Bits 17:16 **PLLP**: Main PLL (PLL) division factor for main system clock

Set and cleared by software to control the frequency of the general PLL output clock. These bits can be written only if PLL is disabled.

**Caution:** The software has to set these bits correctly not to exceed 180 MHz on this domain.

PLL output clock frequency = VCO frequency / PLLP with PLLP = 2, 4, 6, or 8

00: PLLP = 2

01: PLLP = 4

10: PLLP = 6

11: PLLP = 8

Bits 14:6 **PLLN**: Main PLL (PLL) multiplication factor for VCO

Set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when PLL is disabled. Only half-word and word accesses are allowed to write these bits.

**Caution:** The software has to set these bits correctly to ensure that the VCO output frequency is between 100 and 432 MHz.

VCO output frequency = VCO input frequency × PLLN with  $50 \leq \text{PLLN} \leq 432$

00000000: PLLN = 0, wrong configuration

00000001: PLLN = 1, wrong configuration

...

000110010: PLLN = 50

...

001100011: PLLN = 99

001100100: PLLN = 100

...

110110000: PLLN = 432

110110001: PLLN = 433, wrong configuration

...

111111111: PLLN = 511, wrong configuration

*Note: Multiplication factors ranging from 50 and 99 are possible for VCO input frequency higher than 1 MHz. However care must be taken that the minimum VCO output frequency respects the value specified above.*

Bits 5:0 **PLLM**: Division factor for the main PLL (PLL) and audio PLL (PLLI2S) input clock

Set and cleared by software to divide the PLL and PLLI2S input clock before the VCO. These bits can be written only when the PLL and PLLI2S are disabled.

**Caution:** The software has to set these bits correctly to ensure that the VCO input frequency ranges from 1 to 2 MHz. It is recommended to select a frequency of 2 MHz to limit PLL jitter.

VCO input frequency = PLL input clock frequency / PLLM with  $2 \leq \text{PLLM} \leq 63$

000000: PLLM = 0, wrong configuration

000001: PLLM = 1, wrong configuration

000010: PLLM = 2

000011: PLLM = 3

000100: PLLM = 4

...

111110: PLLM = 62

111111: PLLM = 63

### 6.3.3 RCC clock configuration register (RCC\_CFGR)

Address offset: 0x08

Reset value: 0x0000 0000

Access:  $0 \leq \text{wait state} \leq 2$ , word, half-word and byte access

1 or 2 wait states inserted only if the access occurs during a clock source switch.

|            |    |               |            |    |               |          |    |            |      |    |             |      |      |     |     |
|------------|----|---------------|------------|----|---------------|----------|----|------------|------|----|-------------|------|------|-----|-----|
| 31         | 30 | 29            | 28         | 27 | 26            | 25       | 24 | 23         | 22   | 21 | 20          | 19   | 18   | 17  | 16  |
| MCO2       |    | MCO2 PRE[2:0] |            |    | MCO1 PRE[2:0] |          |    | I2SSC<br>R | MCO1 |    | RTCPRE[4:0] |      |      |     |     |
| rw         |    | rw            | rw         | rw | rw            | rw       | rw | rw         | rw   |    | rw          | rw   | rw   | rw  | rw  |

| PPRE2[2:0] |    |               | PPRE1[2:0] |    |               | Reserved |    | HPRE[3:0]  |      |    |             | SWS1 | SWS0 | SW1 | SW0 |
| rw         | rw | rw            | rw         | rw | rw            |          |    | rw         | rw   | rw | rw          | r    | r    | rw  | rw  |

Bits 31:30 **MCO2[1:0]**: Microcontroller clock output 2

Set and cleared by software. Clock source selection may generate glitches on MCO2. It is highly recommended to configure these bits only after reset before enabling the external oscillators and the PLLs.

00: System clock (SYSCLK) selected

01: PLLI2S clock selected

10: HSE oscillator clock selected

11: PLL clock selected

Bits 27:29 **MCO2PRE**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset before enabling the external oscillators and the PLLs.

0xx: no division

100: division by 2

101: division by 3

110: division by 4

111: division by 5

Bits 24:26 **MCO1PRE**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset before enabling the external oscillators and the PLL.

0xx: no division

100: division by 2

101: division by 3

110: division by 4

111: division by 5

Bit 23 **I2SSRC**: I2S clock selection

Set and cleared by software. This bit allows to select the I2S clock source between the PLLI2S clock and the external clock. It is highly recommended to change this bit only after reset and before enabling the I2S module.

0: PLLI2S clock used as I2S clock source

1: External clock mapped on the I2S\_CKIN pin used as I2S clock source

Bits 22:21 **MCO1**: Microcontroller clock output 1

Set and cleared by software. Clock source selection may generate glitches on MCO1. It is highly recommended to configure these bits only after reset before enabling the external oscillators and PLL.

00: HSI clock selected

01: LSE oscillator selected

10: HSE oscillator clock selected

11: PLL clock selected

Bits 20:16 **RTCPRE**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE clock input clock to generate a 1 MHz clock for RTC.

**Caution:** The software has to set these bits correctly to ensure that the clock supplied to the RTC is 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

00000: no clock

00001: no clock

00010: HSE/2

00011: HSE/3

00100: HSE/4

...

11110: HSE/30

11111: HSE/31

Bits 15:13 **PPRE2**: APB high-speed prescaler (APB2)

Set and cleared by software to control APB high-speed clock division factor.

**Caution:** The software has to set these bits correctly not to exceed 90 MHz on this domain. The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after PPRE2 write.

0xx: AHB clock not divided

100: AHB clock divided by 2

101: AHB clock divided by 4

110: AHB clock divided by 8

111: AHB clock divided by 16

Bits 12:10 **PPRE1**: APB Low speed prescaler (APB1)

Set and cleared by software to control APB low-speed clock division factor.

**Caution:** The software has to set these bits correctly not to exceed 45 MHz on this domain. The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after PPRE1 write.

0xx: AHB clock not divided

100: AHB clock divided by 2

101: AHB clock divided by 4

110: AHB clock divided by 8

111: AHB clock divided by 16

Bits 9:8 Reserved, must be kept at reset value.

Bits 7:4 **HPRE**: AHB prescaler

Set and cleared by software to control AHB clock division factor.

**Caution:** The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after HPRE write.

**Caution:** The AHB clock frequency must be at least 25 MHz when the Ethernet is used.

0xxx: system clock not divided  
 1000: system clock divided by 2  
 1001: system clock divided by 4  
 1010: system clock divided by 8  
 1011: system clock divided by 16  
 1100: system clock divided by 64  
 1101: system clock divided by 128  
 1110: system clock divided by 256  
 1111: system clock divided by 512

Bits 3:2 **SWS**: System clock switch status

Set and cleared by hardware to indicate which clock source is used as the system clock.

00: HSI oscillator used as the system clock  
 01: HSE oscillator used as the system clock  
 10: PLL used as the system clock  
 11: not applicable

Bits 1:0 **SW**: System clock switch

Set and cleared by software to select the system clock source.

Set by hardware to force the HSI selection when leaving the Stop or Standby mode or in case of failure of the HSE oscillator used directly or indirectly as the system clock.

00: HSI oscillator selected as system clock  
 01: HSE oscillator selected as system clock  
 10: PLL selected as system clock  
 11: not allowed

### 6.3.4 RCC clock interrupt register (RCC\_CIR)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

| 31           | 30              | 29              | 28           | 27           | 26           | 25           | 24           | 23   | 22             | 21             | 20          | 19          | 18          | 17          | 16          |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CSSC**: Clock security system interrupt clear

This bit is set by software to clear the CSSF flag.

0: No effect

1: Clear CSSF flag

Bit 22 **PLLSAIRDYC**: PLLSAI Ready Interrupt Clear

This bit is set by software to clear PLLSAIRDYF flag. It is reset by hardware when the PLLSAIRDYF is cleared.

0: PLLSAIRDYF not cleared

1: PLLSAIRDYF cleared

Bit 21 **PLLI2SRDYC**: PLLI2S ready interrupt clear

This bit is set by software to clear the PLLI2SRDYF flag.

0: No effect

1: PLLI2SRDYF cleared

Bit 20 **PLLRDYC**: Main PLL(PLL) ready interrupt clear

This bit is set by software to clear the PLLRDYF flag.

0: No effect

1: PLLRDYF cleared

Bit 19 **HSERDYC**: HSE ready interrupt clear

This bit is set by software to clear the HSERDYF flag.

0: No effect

1: HSERDYF cleared

Bit 18 **HSIRDYC**: HSI ready interrupt clear

This bit is set software to clear the HSIRDYF flag.

0: No effect

1: HSIRDYF cleared

Bit 17 **LSERDYC**: LSE ready interrupt clear

This bit is set by software to clear the LSERDYF flag.

0: No effect

1: LSERDYF cleared

Bit 16 **LSIRDYC**: LSI ready interrupt clear

This bit is set by software to clear the LSIRDYF flag.

0: No effect

1: LSIRDYF cleared

Bit 15 Reserved, must be kept at reset value.

Bit 14 **PLLSAIRDYIE**: PLLSAI Ready Interrupt Enable

This bit is set and reset by software to enable/disable interrupt caused by PLLSAI lock.

0: PLLSAI lock interrupt disabled

1: PLLSAI lock interrupt enabled

Bit 13 **PLLI2SRDYIE**: PLLI2S ready interrupt enable

This bit is set and cleared by software to enable/disable interrupt caused by PLLI2S lock.

0: PLLI2S lock interrupt disabled

1: PLLI2S lock interrupt enabled

- Bit 12 **PLLRDYIE**: Main PLL (PLL) ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by PLL lock.  
0: PLL lock interrupt disabled  
1: PLL lock interrupt enabled
- Bit 11 **HSERDYIE**: HSE ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.  
0: HSE ready interrupt disabled  
1: HSE ready interrupt enabled
- Bit 10 **HSIRDYIE**: HSI ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the HSI oscillator stabilization.  
0: HSI ready interrupt disabled  
1: HSI ready interrupt enabled
- Bit 9 **LSERDYIE**: LSE ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.  
0: LSE ready interrupt disabled  
1: LSE ready interrupt enabled
- Bit 8 **LSIRDYIE**: LSI ready interrupt enable  
This bit is set and cleared by software to enable/disable interrupt caused by LSI oscillator stabilization.  
0: LSI ready interrupt disabled  
1: LSI ready interrupt enabled
- Bit 7 **CSSF**: Clock security system interrupt flag  
This bit is set by hardware when a failure is detected in the HSE oscillator.  
It is cleared by software by setting the CSSC bit.  
0: No clock security interrupt caused by HSE clock failure  
1: Clock security interrupt caused by HSE clock failure
- Bit 6 **PLLSAIRDYF**: PLLSAI Ready Interrupt flag  
This bit is set by hardware when the PLLSAI is locked and PLLSAIRDYDIE is set.  
It is cleared by software by setting the PLLSAIRDYC bit.  
0: No clock ready interrupt caused by PLLSAI lock  
1: Clock ready interrupt caused by PLLSAI lock
- Bit 5 **PLLI2SRDYF**: PLLI2S ready interrupt flag  
This bit is set by hardware when the PLLI2S is locked and PLLI2SRDYDIE is set.  
It is cleared by software by setting the PLLI2SRDYC bit.  
0: No clock ready interrupt caused by PLLI2S lock  
1: Clock ready interrupt caused by PLLI2S lock
- Bit 4 **PLLRDYF**: Main PLL (PLL) ready interrupt flag  
This bit is set by hardware when PLL is locked and PLLRDYDIE is set.  
It is cleared by software setting the PLLRDYC bit.  
0: No clock ready interrupt caused by PLL lock  
1: Clock ready interrupt caused by PLL lock

**Bit 3 HSERDYF:** HSE ready interrupt flag

This bit is set by hardware when External High Speed clock becomes stable and HSERDYDIE is set.

It is cleared by software by setting the HSERDYC bit.

0: No clock ready interrupt caused by the HSE oscillator

1: Clock ready interrupt caused by the HSE oscillator

**Bit 2 HSIRDYF:** HSI ready interrupt flag

This bit is set by hardware when the Internal High Speed clock becomes stable and HSIRDYDIE is set.

It is cleared by software by setting the HSIRDYC bit.

0: No clock ready interrupt caused by the HSI oscillator

1: Clock ready interrupt caused by the HSI oscillator

**Bit 1 LSERDYF:** LSE ready interrupt flag

This bit is set by hardware when the External Low Speed clock becomes stable and LSERDYDIE is set.

It is cleared by software by setting the LSERDYC bit.

0: No clock ready interrupt caused by the LSE oscillator

1: Clock ready interrupt caused by the LSE oscillator

**Bit 0 LSIRDYF:** LSI ready interrupt flag

This bit is set by hardware when the internal low speed clock becomes stable and LSIRDYDIE is set.

It is cleared by software by setting the LSIRDYC bit.

0: No clock ready interrupt caused by the LSI oscillator

1: Clock ready interrupt caused by the LSI oscillator

**6.3.5 RCC AHB1 peripheral reset register (RCC\_AHB1RSTR)**

Address offset: 0x10

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |    |          |          |      |          |           |          |          |           |          |          |          |          |          |          |

Bits 31:30 Reserved, must be kept at reset value.

**Bit 29 OTGHSRST:** USB OTG HS module reset

This bit is set and cleared by software.

0: does not reset the USB OTG HS module

1: resets the USB OTG HS module

Bits 28:26 Reserved, must be kept at reset value.

- Bit 25 **ETHMACRST**: Ethernet MAC reset  
This bit is set and cleared by software.  
0: does not reset Ethernet MAC  
1: resets Ethernet MAC
- Bit 24 Reserved, must be kept at reset value.
- Bit 23 **DMA2DRST**: DMA2D reset  
This bit is set and reset by software.  
0: does not reset DMA2D  
1: resets DMA2D
- Bit 22 **DMA2RST**: DMA2 reset  
This bit is set and cleared by software.  
0: does not reset DMA2  
1: resets DMA2
- Bit 21 **DMA1RST**: DMA2 reset  
This bit is set and cleared by software.  
0: does not reset DMA2  
1: resets DMA2
- Bits 20:13 Reserved, must be kept at reset value.
- Bit 12 **CRCRST**: CRC reset  
This bit is set and cleared by software.  
0: does not reset CRC  
1: resets CRC
- Bit 11 Reserved, must be kept at reset value.
- Bit 10 **GPIOKRST**: IO port K reset  
This bit is set and cleared by software.  
0: does not reset IO port K  
1: resets IO port K
- Bit 9 **GPIOJRST**: IO port J reset  
This bit is set and cleared by software.  
0: does not reset IO port J  
1: resets IO port J
- Bit 8 **GPIOIRST**: IO port I reset  
This bit is set and cleared by software.  
0: does not reset IO port I  
1: resets IO port I
- Bit 7 **GPIOHRST**: IO port H reset  
This bit is set and cleared by software.  
0: does not reset IO port H  
1: resets IO port H
- Bit 6 **GPIOGRST**: IO port G reset  
This bit is set and cleared by software.  
0: does not reset IO port G  
1: resets IO port G

- Bit 5 **GPIOFRST**: IO port F reset  
This bit is set and cleared by software.  
0: does not reset IO port F  
1: resets IO port F
- Bit 4 **GPIOERST**: IO port E reset  
This bit is set and cleared by software.  
0: does not reset IO port E  
1: resets IO port E
- Bit 3 **GIODRST**: IO port D reset  
This bit is set and cleared by software.  
0: does not reset IO port D  
1: resets IO port D
- Bit 2 **GPIOCRST**: IO port C reset  
This bit is set and cleared by software.  
0: does not reset IO port C  
1: resets IO port C
- Bit 1 **GPIOBRST**: IO port B reset  
This bit is set and cleared by software.  
0: does not reset IO port B  
1: resets IO port B
- Bit 0 **GPIOARST**: IO port A reset  
This bit is set and cleared by software.  
0: does not reset IO port A  
1: resets IO port A

### 6.3.6 RCC AHB2 peripheral reset register (RCC\_AHB2RSTR)

Address offset: 0x14

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|          |    |    |    |    |    |    |    |              |            |             |             |          |    |    |             |

|          |    |    |    |    |    |    |    | rw           | rw         | rw          | rw          |          |    |    | rw          |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OTGFSRST**: USB OTG FS module reset

Set and cleared by software.

0: does not reset the USB OTG FS module

1: resets the USB OTG FS module

Bit 6 **RNGRST**: Random number generator module reset

Set and cleared by software.

0: does not reset the random number generator module

1: resets the random number generator module

Bit 5 **HASHRST**: Hash module reset

Set and cleared by software.

0: does not reset the HASH module

1: resets the HASH module

Bit 4 **CRYP RST**: Cryptographic module reset

Set and cleared by software.

0: does not reset the cryptographic module

1: resets the cryptographic module

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIRST**: Camera interface reset

Set and cleared by software.

0: does not reset the Camera interface

1: resets the Camera interface

### 6.3.7 RCC AHB3 peripheral reset register (RCC\_AHB3RSTR)

Address offset: 0x18

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |         |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|---------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17      | 16 |

|          |    |    |    |    |    |    |    |    |    |    |    |    |    | rw      |    |

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **FMC RST**: Flexible memory controller module reset

Set and cleared by software.

0: does not reset the FMC module

1: resets the FMC module

### 6.3.8 RCC APB1 peripheral reset register (RCC\_APB1RSTR)

Address offset: 0x20

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|           |           |          |         |          |          |          |           |           |           |          |           |           |           |           |          |

- Bit 31 **UART8RST**: UART8 reset  
Set and cleared by software.  
0: does not reset UART8  
1: resets UART8
- Bit 30 **UART7RST**: UART7 reset  
Set and cleared by software.  
0: does not reset UART7  
1: resets UART7
- Bit 29 **DACRST**: DAC reset  
Set and cleared by software.  
0: does not reset the DAC interface  
1: resets the DAC interface
- Bit 28 **PWRRST**: Power interface reset  
Set and cleared by software.  
0: does not reset the power interface  
1: resets the power interface
- Bit 27 Reserved, must be kept at reset value.
- Bit 26 **CAN2RST**: CAN2 reset  
Set and cleared by software.  
0: does not reset CAN2  
1: resets CAN2
- Bit 25 **CAN1RST**: CAN1 reset  
Set and cleared by software.  
0: does not reset CAN1  
1: resets CAN1
- Bit 24 Reserved, must be kept at reset value.
- Bit 23 **I2C3RST**: I2C3 reset  
Set and cleared by software.  
0: does not reset I2C3  
1: resets I2C3
- Bit 22 **I2C2RST**: I2C2 reset  
Set and cleared by software.  
0: does not reset I2C2  
1: resets I2C2
- Bit 21 **I2C1RST**: I2C1 reset  
Set and cleared by software.  
0: does not reset I2C1  
1: resets I2C1
- Bit 20 **UART5RST**: UART5 reset  
Set and cleared by software.  
0: does not reset UART5  
1: resets UART5
- Bit 19 **UART4RST**: USART4 reset  
Set and cleared by software.  
0: does not reset UART4  
1: resets UART4

- Bit 18 **USART3RST**: USART3 reset  
Set and cleared by software.  
0: does not reset USART3  
1: resets USART3
- Bit 17 **USART2RST**: USART2 reset  
Set and cleared by software.  
0: does not reset USART2  
1: resets USART2
- Bit 16 Reserved, must be kept at reset value.
- Bit 15 **SPI3RST**: SPI3 reset  
Set and cleared by software.  
0: does not reset SPI3  
1: resets SPI3
- Bit 14 **SPI2RST**: SPI2 reset  
Set and cleared by software.  
0: does not reset SPI2  
1: resets SPI2
- Bits 13:12 Reserved, must be kept at reset value.
- Bit 11 **WWDGRST**: Window watchdog reset  
Set and cleared by software.  
0: does not reset the window watchdog  
1: resets the window watchdog
- Bits 10:9 Reserved, must be kept at reset value.
- Bit 8 **TIM14RST**: TIM14 reset  
Set and cleared by software.  
0: does not reset TIM14  
1: resets TIM14
- Bit 7 **TIM13RST**: TIM13 reset  
Set and cleared by software.  
0: does not reset TIM13  
1: resets TIM13
- Bit 6 **TIM12RST**: TIM12 reset  
Set and cleared by software.  
0: does not reset TIM12  
1: resets TIM12
- Bit 5 **TIM7RST**: TIM7 reset  
Set and cleared by software.  
0: does not reset TIM7  
1: resets TIM7
- Bit 4 **TIM6RST**: TIM6 reset  
Set and cleared by software.  
0: does not reset TIM6  
1: resets TIM6

- Bit 3 **TIM5RST**: TIM5 reset  
Set and cleared by software.  
0: does not reset TIM5  
1: resets TIM5
- Bit 2 **TIM4RST**: TIM4 reset  
Set and cleared by software.  
0: does not reset TIM4  
1: resets TIM4
- Bit 1 **TIM3RST**: TIM3 reset  
Set and cleared by software.  
0: does not reset TIM3  
1: resets TIM3
- Bit 0 **TIM2RST**: TIM2 reset  
Set and cleared by software.  
0: does not reset TIM2  
1: resets TIM2

### 6.3.9 RCC APB2 peripheral reset register (RCC\_APB2RSTR)

Address offset: 0x24

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|               |                |             |             |             |             |          |            |          |             |                   |                   |          |              |              |             |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **LTD CRST**: LTDC reset

This bit is set and reset by software.

0: does not reset LCD-TFT

1: resets LCD-TFT

Bits 27:23 Reserved, must be kept at reset value.

Bit 22 **SAI1RST**: SAI1 reset

This bit is set and reset by software.

0: does not reset SAI1

1: resets SAI1

Bit 21 **SPI6RST**: SPI6 reset

This bit is set and cleared by software.

0: does not reset SPI6

1: resets SPI6

Bit 20 **SPI5RST**: SPI5 reset

This bit is set and cleared by software.

0: does not reset SPI5

1: resets SPI5

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM11RST**: TIM11 reset

This bit is set and cleared by software.

0: does not reset TIM11

1: resets TIM14

Bit 17 **TIM10RST**: TIM10 reset

This bit is set and cleared by software.

0: does not reset TIM10

1: resets TIM10

Bit 16 **TIM9RST**: TIM9 reset

This bit is set and cleared by software.

0: does not reset TIM9

1: resets TIM9

Bit 15 Reserved, must be kept at reset value.

Bit 14 **SYSCFGRST**: System configuration controller reset  
This bit is set and cleared by software.  
0: does not reset the System configuration controller  
1: resets the System configuration controller

Bit 13 **SPI4RST**: SPI4 reset  
This bit is set and cleared by software.  
0: does not reset SPI4  
1: resets SPI4

Bit 12 **SPI1RST**: SPI1 reset  
This bit is set and cleared by software.  
0: does not reset SPI1  
1: resets SPI1

Bit 11 **SDIORST**: SDIO reset  
This bit is set and cleared by software.  
0: does not reset the SDIO module  
1: resets the SDIO module

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **ADCRST**: ADC interface reset (common to all ADCs)  
This bit is set and cleared by software.  
0: does not reset the ADC interface  
1: resets the ADC interface

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **USART6RST**: USART6 reset  
This bit is set and cleared by software.  
0: does not reset USART6  
1: resets USART6

Bit 4 **USART1RST**: USART1 reset  
This bit is set and cleared by software.  
0: does not reset USART1  
1: resets USART1

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8RST**: TIM8 reset  
This bit is set and cleared by software.  
0: does not reset TIM8  
1: resets TIM8

Bit 0 **TIM1RST**: TIM1 reset  
This bit is set and cleared by software.  
0: does not reset TIM1  
1: resets TIM1

### 6.3.10 RCC AHB1 peripheral clock register (RCC\_AHB1ENR)

Address offset: 0x30

Reset value: 0x0010 0000

Access: no wait state, word, half-word and byte access.

| 31       | 30              | 29           | 28             | 27             | 26             | 25          | 24          | 23          | 22          | 21      | 20               | 19          | 18            | 17          | 16          |

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OTGHSULPIEN**: USB OTG HSULPI clock enable

This bit is set and cleared by software. It must be cleared when the OTG\_HS is used in FS mode.

0: USB OTG HS ULPI clock disabled

1: USB OTG HS ULPI clock enabled

Bit 29 **OTGHSSEN**: USB OTG HS clock enable

This bit is set and cleared by software.

0: USB OTG HS clock disabled

1: USB OTG HS clock enabled

Bit 28 **ETHMACPTEN**: Ethernet PTP clock enable

This bit is set and cleared by software.

0: Ethernet PTP clock disabled

1: Ethernet PTP clock enabled

Bit 27 **ETHMACRXEN**: Ethernet Reception clock enable

This bit is set and cleared by software.

0: Ethernet Reception clock disabled

1: Ethernet Reception clock enabled

Bit 26 **ETHMACTXEN**: Ethernet Transmission clock enable

This bit is set and cleared by software.

0: Ethernet Transmission clock disabled

1: Ethernet Transmission clock enabled

Bit 25 **ETHMACEN**: Ethernet MAC clock enable

This bit is set and cleared by software.

0: Ethernet MAC clock disabled

1: Ethernet MAC clock enabled

Bit 24 Reserved, must be kept at reset value.

Bit 23 **DMA2DEN**: DMA2D clock enable

This bit is set and cleared by software.

0: DMA2D clock disabled

1: DMA2D clock enabled

- Bit 22 **DMA2EN**: DMA2 clock enable  
This bit is set and cleared by software.  
0: DMA2 clock disabled  
1: DMA2 clock enabled
- Bit 21 **DMA1EN**: DMA1 clock enable  
This bit is set and cleared by software.  
0: DMA1 clock disabled  
1: DMA1 clock enabled
- Bit 20 **CCMDATARAMEN**: CCM data RAM clock enable  
This bit is set and cleared by software.  
0: CCM data RAM clock disabled  
1: CCM data RAM clock enabled
- Bit 19 Reserved, must be kept at reset value.
- Bit 18 **BKPSRAMEN**: Backup SRAM interface clock enable  
This bit is set and cleared by software.  
0: Backup SRAM interface clock disabled  
1: Backup SRAM interface clock enabled
- Bits 17:13 Reserved, must be kept at reset value.
- Bit 12 **CRCEN**: CRC clock enable  
This bit is set and cleared by software.  
0: CRC clock disabled  
1: CRC clock enabled
- Bit 11 Reserved, must be kept at reset value.
- Bit 10 **GPIOKEN**: IO port K clock enable  
This bit is set and cleared by software.  
0: IO port K clock disabled  
1: IO port K clock enabled
- Bit 9 **GPIOJEN**: IO port J clock enable  
This bit is set and cleared by software.  
0: IO port J clock disabled  
1: IO port J clock enabled
- Bit 8 **GPIOIEN**: IO port I clock enable  
This bit is set and cleared by software.  
0: IO port I clock disabled  
1: IO port I clock enabled
- Bit 7 **GPIOHEN**: IO port H clock enable  
This bit is set and cleared by software.  
0: IO port H clock disabled  
1: IO port H clock enabled
- Bit 6 **GPIOGEN**: IO port G clock enable  
This bit is set and cleared by software.  
0: IO port G clock disabled  
1: IO port G clock enabled

- Bit 5 **GPIOFEN**: IO port F clock enable  
 This bit is set and cleared by software.  
 0: IO port F clock disabled  
 1: IO port F clock enabled
- Bit 4 **GPIOEEN**: IO port E clock enable  
 This bit is set and cleared by software.  
 0: IO port E clock disabled  
 1: IO port E clock enabled
- Bit 3 **GPIODEN**: IO port D clock enable  
 This bit is set and cleared by software.  
 0: IO port D clock disabled  
 1: IO port D clock enabled
- Bit 2 **GPIOCEN**: IO port C clock enable  
 This bit is set and cleared by software.  
 0: IO port C clock disabled  
 1: IO port C clock enabled
- Bit 1 **GPIOBEN**: IO port B clock enable  
 This bit is set and cleared by software.  
 0: IO port B clock disabled  
 1: IO port B clock enabled
- Bit 0 **GPIOAEN**: IO port A clock enable  
 This bit is set and cleared by software.  
 0: IO port A clock disabled  
 1: IO port A clock enabled

### 6.3.11 RCC AHB2 peripheral clock enable register (RCC\_AHB2ENR)

Address offset: 0x34

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

Bits 31:8 Reserved, must be kept at reset value.

- Bit 7 **OTGFSEN**: USB OTG FS clock enable  
 This bit is set and cleared by software.  
 0: USB OTG FS clock disabled  
 1: USB OTG FS clock enabled

- Bit 6 **RNGEN**: Random number generator clock enable  
 This bit is set and cleared by software.  
 0: Random number generator clock disabled  
 1: Random number generator clock enabled

Bit 5 **HASHEN**: Hash modules clock enable

This bit is set and cleared by software.

0: Hash modules clock disabled

1: Hash modules clock enabled

Bit 4 **CRYPEN**: Cryptographic modules clock enable

This bit is set and cleared by software.

0: cryptographic module clock disabled

1: cryptographic module clock enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIEN**: Camera interface enable

This bit is set and cleared by software.

0: Camera interface clock disabled

1: Camera interface clock enabled

### 6.3.12 RCC AHB3 peripheral clock enable register (RCC\_AHB3ENR)

Address offset: 0x38

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |

This bit is set and cleared by software.  
0: I2C1 clock disabled  
1: I2C1 clock enabled
- Bit 20 **UART5EN**: UART5 clock enable  
This bit is set and cleared by software.  
0: UART5 clock disabled  
1: UART5 clock enabled
- Bit 19 **UART4EN**: UART4 clock enable  
This bit is set and cleared by software.  
0: UART4 clock disabled  
1: UART4 clock enabled

- Bit 18 **USART3EN**: USART3 clock enable  
This bit is set and cleared by software.  
0: USART3 clock disabled  
1: USART3 clock enabled
- Bit 17 **USART2EN**: USART2 clock enable  
This bit is set and cleared by software.  
0: USART2 clock disabled  
1: USART2 clock enabled
- Bit 16 Reserved, must be kept at reset value.
- Bit 15 **SPI3EN**: SPI3 clock enable  
This bit is set and cleared by software.  
0: SPI3 clock disabled  
1: SPI3 clock enabled
- Bit 14 **SPI2EN**: SPI2 clock enable  
This bit is set and cleared by software.  
0: SPI2 clock disabled  
1: SPI2 clock enabled
- Bits 13:12 Reserved, must be kept at reset value.
- Bit 11 **WWDGEN**: Window watchdog clock enable  
This bit is set and cleared by software.  
0: Window watchdog clock disabled  
1: Window watchdog clock enabled
- Bit 10:9 Reserved, must be kept at reset value.
- Bit 8 **TIM14EN**: TIM14 clock enable  
This bit is set and cleared by software.  
0: TIM14 clock disabled  
1: TIM14 clock enabled
- Bit 7 **TIM13EN**: TIM13 clock enable  
This bit is set and cleared by software.  
0: TIM13 clock disabled  
1: TIM13 clock enabled
- Bit 6 **TIM12EN**: TIM12 clock enable  
This bit is set and cleared by software.  
0: TIM12 clock disabled  
1: TIM12 clock enabled
- Bit 5 **TIM7EN**: TIM7 clock enable  
This bit is set and cleared by software.  
0: TIM7 clock disabled  
1: TIM7 clock enabled
- Bit 4 **TIM6EN**: TIM6 clock enable  
This bit is set and cleared by software.  
0: TIM6 clock disabled  
1: TIM6 clock enabled

Bit 3 **TIM5EN**: TIM5 clock enable

This bit is set and cleared by software.

0: TIM5 clock disabled

1: TIM5 clock enabled

Bit 2 **TIM4EN**: TIM4 clock enable

This bit is set and cleared by software.

0: TIM4 clock disabled

1: TIM4 clock enabled

Bit 1 **TIM3EN**: TIM3 clock enable

This bit is set and cleared by software.

0: TIM3 clock disabled

1: TIM3 clock enabled

Bit 0 **TIM2EN**: TIM2 clock enable

This bit is set and cleared by software.

0: TIM2 clock disabled

1: TIM2 clock enabled

### 6.3.14 RCC APB2 peripheral clock enable register (RCC\_APB2ENR)

Address offset: 0x44

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

| 31            | 30            | 29         | 28         | 27         | 26         | 25         | 24         | 23       | 22               | 21               | 20       | 19   | 18          | 17          | 16         |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **LTDCEN**: LTDC clock enable

This bit is set and cleared by software.

0: LTDC clock disabled

1: LTDC clock enabled

Bits 27: 23 Reserved, must be kept at reset value.

Bit 22 **SAI1EN**: SAI1 clock enable

This bit is set and cleared by software.

0: SAI1 clock disabled

1: SAI1 clock enabled

Bit 21 **SPI6EN**: SPI6 clock enable

This bit is set and cleared by software.

0: SPI6 clock disabled

1: SPI6 clock enabled

Bit 20 **SPI5EN**: SPI5 clock enable

This bit is set and cleared by software.

0: SPI5 clock disabled

1: SPI5 clock enabled

Bit 18 **TIM11EN**: TIM11 clock enable

This bit is set and cleared by software.

0: TIM11 clock disabled

1: TIM11 clock enabled

Bit 17 **TIM10EN**: TIM10 clock enable

This bit is set and cleared by software.

0: TIM10 clock disabled

1: TIM10 clock enabled

Bit 16 **TIM9EN**: TIM9 clock enable

This bit is set and cleared by software.

0: TIM9 clock disabled

1: TIM9 clock enabled

Bit 15 Reserved, must be kept at reset value.

- Bit 14 **SYSCFGEN**: System configuration controller clock enable  
This bit is set and cleared by software.  
0: System configuration controller clock disabled  
1: System configuration controller clock enabled
- Bit 13 **SPI4EN**: SPI4 clock enable  
This bit is set and cleared by software.  
0: SPI4 clock disabled  
1: SPI4 clock enabled
- Bit 12 **SPI1EN**: SPI1 clock enable  
This bit is set and cleared by software.  
0: SPI1 clock disabled  
1: SPI1 clock enabled
- Bit 11 **SDIOEN**: SDIO clock enable  
This bit is set and cleared by software.  
0: SDIO module clock disabled  
1: SDIO module clock enabled
- Bit 10 **ADC3EN**: ADC3 clock enable  
This bit is set and cleared by software.  
0: ADC3 clock disabled

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OTGHSULPILPEN**: USB OTG HS ULPI clock enable during Sleep mode

This bit is set and cleared by software. It must be cleared when the OTG\_HS is used in FS mode.

0: USB OTG HS ULPI clock disabled during Sleep mode  
1: USB OTG HS ULPI clock enabled during Sleep mode

Bit 29 **OTGHS LPEN**: USB OTG HS clock enable during Sleep mode

This bit is set and cleared by software.

0: USB OTG HS clock disabled during Sleep mode  
1: USB OTG HS clock enabled during Sleep mode

Bit 28 **ETHMACPTLPEN**: Ethernet PTP clock enable during Sleep mode

This bit is set and cleared by software.

0: Ethernet PTP clock disabled during Sleep mode  
1: Ethernet PTP clock enabled during Sleep mode

Bit 27 **ETHMACRXLPEN**: Ethernet reception clock enable during Sleep mode

This bit is set and cleared by software.

0: Ethernet reception clock disabled during Sleep mode  
1: Ethernet reception clock enabled during Sleep mode

Bit 26 **ETHMACTXLPEN**: Ethernet transmission clock enable during Sleep mode

This bit is set and cleared by software.

0: Ethernet transmission clock disabled during sleep mode  
1: Ethernet transmission clock enabled during sleep mode

Bit 25 **ETHMACLPEN**: Ethernet MAC clock enable during Sleep mode

This bit is set and cleared by software.

0: Ethernet MAC clock disabled during Sleep mode  
1: Ethernet MAC clock enabled during Sleep mode

Bit 24 Reserved, must be kept at reset value.

- Bit 23 **DMA2DLPEN**: DMA2D clock enable during Sleep mode  
This bit is set and cleared by software.  
0: DMA2D clock disabled during Sleep mode  
1: DMA2D clock enabled during Sleep mode
- Bit 22 **DMA2LPEN**: DMA2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: DMA2 clock disabled during Sleep mode  
1: DMA2 clock enabled during Sleep mode
- Bit 21 **DMA1LPEN**: DMA1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: DMA1 clock disabled during Sleep mode  
1: DMA1 clock enabled during Sleep mode
- Bit 20 Reserved, must be kept at reset value.
- Bit 19 **SRAM3LPEN**: SRAM3 interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SRAM3 interface clock disabled during Sleep mode  
1: SRAM3 interface clock enabled during Sleep mode
- Bit 18 **BKPSRAMLPEN**: Backup SRAM interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: Backup SRAM interface clock disabled during Sleep mode  
1: Backup SRAM interface clock enabled during Sleep mode
- Bit 17 **SRAM2LPEN**: SRAM2 interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SRAM2 interface clock disabled during Sleep mode  
1: SRAM2 interface clock enabled during Sleep mode
- Bit 16 **SRAM1LPEN**: SRAM1 interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SRAM1 interface clock disabled during Sleep mode  
1: SRAM1 interface clock enabled during Sleep mode
- Bit 15 **FLITFLPEN**: Flash interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: Flash interface clock disabled during Sleep mode  
1: Flash interface clock enabled during Sleep mode
- Bits 14:13 Reserved, must be kept at reset value.
- Bit 12 **CRCLPEN**: CRC clock enable during Sleep mode  
This bit is set and cleared by software.  
0: CRC clock disabled during Sleep mode  
1: CRC clock enabled during Sleep mode
- Bit 11 Reserved, must be kept at reset value.
- Bit 10 **GPIOKLPEN**: IO port K clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port K clock disabled during Sleep mode  
1: IO port K clock enabled during Sleep mode

- Bit 9 **GPIOJLPEN**: IO port J clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port J clock disabled during Sleep mode  
1: IO port J clock enabled during Sleep mode
- Bit 8 **GPIOILPEN**: IO port I clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port I clock disabled during Sleep mode  
1: IO port I clock enabled during Sleep mode
- Bit 7 **GPIOHLPEN**: IO port H clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port H clock disabled during Sleep mode  
1: IO port H clock enabled during Sleep mode
- Bits 6 **GPIOGLPEN**: IO port G clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port G clock disabled during Sleep mode  
1: IO port G clock enabled during Sleep mode
- Bit 5 **GPIOFLPEN**: IO port F clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port F clock disabled during Sleep mode  
1: IO port F clock enabled during Sleep mode
- Bit 4 **GPIOELPEN**: IO port E clock enable during Sleep mode  
Set and cleared by software.  
0: IO port E clock disabled during Sleep mode  
1: IO port E clock enabled during Sleep mode
- Bit 3 **GIODLPEN**: IO port D clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port D clock disabled during Sleep mode  
1: IO port D clock enabled during Sleep mode
- Bit 2 **GPIOCLPEN**: IO port C clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port C clock disabled during Sleep mode  
1: IO port C clock enabled during Sleep mode
- Bit 1 **GPIOBLPEN**: IO port B clock enable during Sleep mode  
This bit is set and cleared by software.  
0: IO port B clock disabled during Sleep mode  
1: IO port B clock enabled during Sleep mode
- Bit 0 **GPIOALPEN**: IO port A clock enable during sleep mode  
This bit is set and cleared by software.  
0: IO port A clock disabled during Sleep mode  
1: IO port A clock enabled during Sleep mode

### 6.3.16 RCC AHB2 peripheral clock enable in low power mode register (RCC\_AHB2LPENR)

Address offset: 0x54

Reset value: 0x0000 00F1

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |               |             |              |              |          |    |    |              |

|          |    |    |    |    |    |    |    | rw            | rw          | rw           | rw           |          |    |    | rw           |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OTGFSLPEN**: USB OTG FS clock enable during Sleep mode

This bit is set and cleared by software.

0: USB OTG FS clock disabled during Sleep mode

1: USB OTG FS clock enabled during Sleep mode

Bit 6 **RNGLPEN**: Random number generator clock enable during Sleep mode

This bit is set and cleared by software.

0: Random number generator clock disabled during Sleep mode

1: Random number generator clock enabled during Sleep mode

Bit 5 **HASHLPEN**: Hash modules clock enable during Sleep mode

This bit is set and cleared by software.

0: Hash modules clock disabled during Sleep mode

1: Hash modules clock enabled during Sleep mode

Bit 4 **CRYPLPEN**: Cryptography modules clock enable during Sleep mode

This bit is set and cleared by software.

0: cryptography modules clock disabled during Sleep mode

1: cryptography modules clock enabled during Sleep mode

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMILPEN**: Camera interface enable during Sleep mode

This bit is set and cleared by software.

0: Camera interface clock disabled during Sleep mode

1: Camera interface clock enabled during Sleep mode

### 6.3.17 RCC AHB3 peripheral clock enable in low power mode register (RCC\_AHB3LPENR)

Address offset: 0x58

Reset value: 0x0000 0001

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |

- Bit 31 **UART8LPEN**: UART8 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: UART8 clock disabled during Sleep mode  
1: UART8 clock enabled during Sleep mode
- Bit 30 **UART7LPEN**: UART7 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: UART7 clock disabled during Sleep mode  
1: UART7 clock enabled during Sleep mode
- Bit 29 **DACLPE**: DAC interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: DAC interface clock disabled during Sleep mode  
1: DAC interface clock enabled during Sleep mode
- Bit 28 **PWRLPEN**: Power interface clock enable during Sleep mode  
This bit is set and cleared by software.  
0: Power interface clock disabled during Sleep mode  
1: Power interface clock enabled during Sleep mode
- Bit 27 Reserved, must be kept at reset value.
- Bit 26 **CAN2LPEN**: CAN 2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: CAN 2 clock disabled during sleep mode  
1: CAN 2 clock enabled during sleep mode
- Bit 25 **CAN1LPEN**: CAN 1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: CAN 1 clock disabled during Sleep mode  
1: CAN 1 clock enabled during Sleep mode
- Bit 24 Reserved, must be kept at reset value.
- Bit 23 **I2C3LPEN**: I2C3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I2C3 clock disabled during Sleep mode  
1: I2C3 clock enabled during Sleep mode
- Bit 22 **I2C2LPEN**: I2C2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I2C2 clock disabled during Sleep mode  
1: I2C2 clock enabled during Sleep mode
- Bit 21 **I2C1LPEN**: I2C1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: I2C1 clock disabled during Sleep mode  
1: I2C1 clock enabled during Sleep mode
- Bit 20 **UART5LPEN**: UART5 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: UART5 clock disabled during Sleep mode  
1: UART5 clock enabled during Sleep mode
- Bit 19 **UART4LPEN**: UART4 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: UART4 clock disabled during Sleep mode  
1: UART4 clock enabled during Sleep mode

- Bit 18 **USART3LPEN**: USART3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART3 clock disabled during Sleep mode  
1: USART3 clock enabled during Sleep mode
- Bit 17 **USART2LPEN**: USART2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART2 clock disabled during Sleep mode  
1: USART2 clock enabled during Sleep mode
- Bit 16 Reserved, must be kept at reset value.
- Bit 15 **SPI3LPEN**: SPI3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SPI3 clock disabled during Sleep mode  
1: SPI3 clock enabled during Sleep mode
- Bit 14 **SPI2LPEN**: SPI2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SPI2 clock disabled during Sleep mode  
1: SPI2 clock enabled during Sleep mode
- Bits 13:12 Reserved, must be kept at reset value.
- Bit 11 **WWDGLPEN**: Window watchdog clock enable during Sleep mode  
This bit is set and cleared by software.  
0: Window watchdog clock disabled during sleep mode  
1: Window watchdog clock enabled during sleep mode
- Bits 10:9 Reserved, must be kept at reset value.
- Bit 8 **TIM14LPEN**: TIM14 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM14 clock disabled during Sleep mode  
1: TIM14 clock enabled during Sleep mode
- Bit 7 **TIM13LPEN**: TIM13 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM13 clock disabled during Sleep mode  
1: TIM13 clock enabled during Sleep mode
- Bit 6 **TIM12LPEN**: TIM12 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM12 clock disabled during Sleep mode  
1: TIM12 clock enabled during Sleep mode
- Bit 5 **TIM7LPEN**: TIM7 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM7 clock disabled during Sleep mode  
1: TIM7 clock enabled during Sleep mode
- Bit 4 **TIM6LPEN**: TIM6 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM6 clock disabled during Sleep mode  
1: TIM6 clock enabled during Sleep mode

- Bit 3 **TIM5LPEN**: TIM5 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM5 clock disabled during Sleep mode  
1: TIM5 clock enabled during Sleep mode
- Bit 2 **TIM4LPEN**: TIM4 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM4 clock disabled during Sleep mode  
1: TIM4 clock enabled during Sleep mode
- Bit 1 **TIM3LPEN**: TIM3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM3 clock disabled during Sleep mode  
1: TIM3 clock enabled during Sleep mode
- Bit 0 **TIM2LPEN**: TIM2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: TIM2 clock disabled during Sleep mode  
1: TIM2 clock enabled during Sleep mode

### 6.3.19 RCC APB2 peripheral clock enabled in low power mode register (RCC\_APB2LPENR)

Address offset: 0x64

Reset value: 0x0x0477 7F33

Access: no wait state, word, half-word and byte access.

|          |              |           |           |           |           |           |           |          |              |              |           |          |            |            |           |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **LTDC LPEN**: LTDC clock enable during Sleep mode

This bit is set and cleared by software.

0: LTDC clock disabled during Sleep mode

1: LTDC clock enabled during Sleep mode

Bits 25:23 Reserved, must be kept at reset value.

Bit 22 **SAI1 LPEN**: SAI1 clock enable during Sleep mode

This bit is set and cleared by software.

0: SAI1 clock disabled during Sleep mode

1: SAI1 clock enabled during Sleep mode

Bit 21 **SPI6 LPEN**: SPI6 clock enable during Sleep mode

This bit is set and cleared by software.

0: SPI6 clock disabled during Sleep mode

1: SPI6 clock enabled during Sleep mode

Bit 20 **SPI5 LPEN**: SPI5 clock enable during Sleep mode

This bit is set and cleared by software.

0: SPI5 clock disabled during Sleep mode

1: SPI5 clock enabled during Sleep mode

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM11 LPEN**: TIM11 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM11 clock disabled during Sleep mode

1: TIM11 clock enabled during Sleep mode

Bit 17 **TIM10 LPEN**: TIM10 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM10 clock disabled during Sleep mode

1: TIM10 clock enabled during Sleep mode

- Bit 16 **TIM9LPEN**: TIM9 clock enable during sleep mode  
This bit is set and cleared by software.  
0: TIM9 clock disabled during Sleep mode  
1: TIM9 clock enabled during Sleep mode
- Bit 15 Reserved, must be kept at reset value.
- Bit 14 **SYSCFGLPEN**: System configuration controller clock enable during Sleep mode  
This bit is set and cleared by software.  
0: System configuration controller clock disabled during Sleep mode  
1: System configuration controller clock enabled during Sleep mode
- Bit 13 **SPI4LPEN**: SPI4 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SPI4 clock disabled during Sleep mode  
1: SPI4 clock enabled during Sleep mode
- Bit 12 **SPI1LPEN**: SPI1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SPI1 clock disabled during Sleep mode  
1: SPI1 clock enabled during Sleep mode
- Bit 11 **SDIOLPEN**: SDIO clock enable during Sleep mode  
This bit is set and cleared by software.  
0: SDIO module clock disabled during Sleep mode  
1: SDIO module clock enabled during Sleep mode
- Bit 10 **ADC3LPEN**: ADC 3 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: ADC 3 clock disabled during Sleep mode  
1: ADC 3 clock disabled during Sleep mode
- Bit 9 **ADC2LPEN**: ADC2 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: ADC2 clock disabled during Sleep mode  
1: ADC2 clock disabled during Sleep mode
- Bit 8 **ADC1LPEN**: ADC1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: ADC1 clock disabled during Sleep mode  
1: ADC1 clock disabled during Sleep mode
- Bits 7:6 Reserved, must be kept at reset value.
- Bit 5 **USART6LPEN**: USART6 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART6 clock disabled during Sleep mode  
1: USART6 clock enabled during Sleep mode
- Bit 4 **USART1LPEN**: USART1 clock enable during Sleep mode  
This bit is set and cleared by software.  
0: USART1 clock disabled during Sleep mode  
1: USART1 clock enabled during Sleep mode

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8LPEN**: TIM8 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM8 clock disabled during Sleep mode

1: TIM8 clock enabled during Sleep mode

Bit 0 **TIM1LPEN**: TIM1 clock enable during Sleep mode

This bit is set and cleared by software.

0: TIM1 clock disabled during Sleep mode

1: TIM1 clock enabled during Sleep mode

### 6.3.20 RCC Backup domain control register (RCC\_BDCR)

Address offset: 0x70

Reset value: 0x0000 0000, reset by Backup domain reset.

Access:  $0 \leq \text{wait state} \leq 3$ , word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

The LSEON, LSEBYP, RTCSEL and RTCEN bits in the [RCC Backup domain control register \(RCC\\_BDCR\)](#) are in the Backup domain. As a result, after Reset, these bits are write-protected and the DBP bit in the [PWR power control register \(PWR\\_CR\)](#) for [STM32F42xxx and STM32F43xxx](#) has to be set before these can be modified. Refer to [Section 6.1.1: System reset on page 150](#) for further information. These bits are only reset after a Backup domain Reset (see [Section 6.1.3: Backup domain reset](#)). Any internal or external Reset will not have any effect on these bits.

|          |          |    |    |    |    |             |    |          |    |    |    |    |        |       |       |

| 31       | 30       | 29 | 28 | 27 | 26 | 25          | 24 | 23       | 22 | 21 | 20 | 19 | 18     | 17    | 16    |
| Reserved |          |    |    |    |    |             |    |          |    |    |    |    |        |       | BDRST |
|          |          |    |    |    |    |             |    |          |    |    |    |    |        |       | rw    |
| 15       | 14       | 13 | 12 | 11 | 10 | 9           | 8  | 7        | 6  | 5  | 4  | 3  | 2      | 1     | 0     |
| RTCEN    | Reserved |    |    |    |    | RTCSEL[1:0] |    | Reserved |    |    |    |    | LSEBYP | LSEON |       |
| rw       |          |    |    |    |    | rw          | rw |          |    |    |    |    | rw     | r     | rw    |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset

This bit is set and cleared by software.

0: Reset not activated

1: Resets the entire Backup domain

*Note: The BKPSRAM is not affected by this reset, the only way of resetting the BKPSRAM is through the Flash interface when a protection level change from level 1 to level 0 is requested.*

Bit 15 **RTCEN**: RTC clock enable

This bit is set and cleared by software.

0: RTC clock disabled

1: RTC clock enabled

Bits 14:10 Reserved, must be kept at reset value.

**Bits 9:8 RTCSEL[1:0]:** RTC clock source selection

These bits are set by software to select the clock source for the RTC. Once the RTC clock source has been selected, it cannot be changed anymore unless the Backup domain is reset. The BDRST bit can be used to reset them.

00: No clock

01: LSE oscillator clock used as the RTC clock

10: LSI oscillator clock used as the RTC clock

11: HSE oscillator clock divided by a programmable prescaler (selection through the RTCPRE[4:0] bits in the RCC clock configuration register (RCC\_CFGR)) used as the RTC clock

**Bits 7:3** Reserved, must be kept at reset value.

**Bit 2 LSEBYP:** External low-speed oscillator bypass

This bit is set and cleared by software to bypass the oscillator. This bit can be written only when the LSE clock is disabled.

0: LSE oscillator not bypassed

1: LSE oscillator bypassed

**Bit 1 LSERDY:** External low-speed oscillator ready

This bit is set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after 6 external low-speed oscillator clock cycles.

0: LSE clock not ready

1: LSE clock ready

**Bit 0 LSEON:** External low-speed oscillator enable

This bit is set and cleared by software.

0: LSE clock OFF

1: LSE clock ON

**6.3.21 RCC clock control & status register (RCC\_CSR)**

Address offset: 0x74

Reset value: 0x0E00 0000, reset by system reset, except reset flags by power reset only.

Access:  $0 \leq \text{wait state} \leq 3$ , word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

|              |              |              |             |             |             |             |      |          |    |    |    |    |        |       |    |
|--------------|--------------|--------------|-------------|-------------|-------------|-------------|------|----------|----|----|----|----|--------|-------|----|

|              |              |              |             |             |             |             |      |          |    |    |    |    | r      | rw    |    |

**Bit 31 LPWRRSTF:** Low-power reset flag

This bit is set by hardware when a Low-power management reset occurs.

Cleared by writing to the RMVF bit.

0: No Low-power management reset occurred

1: Low-power management reset occurred

For further information on Low-power management reset, refer to [Low-power management reset](#).

**Bit 30 WWDGRSTF:** Window watchdog reset flag

This bit is set by hardware when a window watchdog reset occurs.

Cleared by writing to the RMVF bit.

0: No window watchdog reset occurred

1: Window watchdog reset occurred

**Bit 29 IWDGRSTF:** Independent watchdog reset flag

This bit is set by hardware when an independent watchdog reset from  $V_{DD}$  domain occurs.

Cleared by writing to the RMVF bit.

0: No watchdog reset occurred

1: Watchdog reset occurred

**Bit 28 SFTRSTF:** Software reset flag

This bit is set by hardware when a software reset occurs.

Cleared by writing to the RMVF bit.

0: No software reset occurred

1: Software reset occurred

**Bit 27 PORRSTF:** POR/PDR reset flag

This bit is set by hardware when a POR/PDR reset occurs.

Cleared by writing to the RMVF bit.

0: No POR/PDR reset occurred

1: POR/PDR reset occurred

**Bit 26 PINRSTF:** PIN reset flag

This bit is set by hardware when a reset from the NRST pin occurs.

Cleared by writing to the RMVF bit.

0: No reset from NRST pin occurred

1: Reset from NRST pin occurred

**Bit 25 BORRSTF:** BOR reset flag

Cleared by software by writing the RMVF bit.

This bit is set by hardware when a POR/PDR or BOR reset occurs.

0: No POR/PDR or BOR reset occurred

1: POR/PDR or BOR reset occurred

**Bit 24 RMVF:** Remove reset flag

This bit is set by software to clear the reset flags.

0: No effect

1: Clear the reset flags

Bits 23:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: Internal low-speed oscillator ready

This bit is set and cleared by hardware to indicate when the internal RC 40 kHz oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after 3 LSI clock cycles.

0: LSI RC oscillator not ready

1: LSI RC oscillator ready

Bit 0 **LSION**: Internal low-speed oscillator enable

This bit is set and cleared by software.

0: LSI RC oscillator OFF

1: LSI RC oscillator ON

### 6.3.22 RCC spread spectrum clock generation register (RCC\_SSCGR)

Address offset: 0x80

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

The spread spectrum clock generation is available only for the main PLL.

The RCC\_SSCGR register must be written either before the main PLL is enabled or after the main PLL disabled.

**Note:** For full details about PLL spread spectrum clock generation (SSCG) characteristics, refer to the “Electrical characteristics” section in your device datasheet.

|            |                   |          |    |         |    |    |    |    |    |    |    |    |    |    |    |

Bit 31 **SSCGEN**: Spread spectrum modulation enable

This bit is set and cleared by software.

0: Spread spectrum modulation DISABLE. (To write after clearing CR[24]=PLLON bit)

1: Spread spectrum modulation ENABLE. (To write before setting CR[24]=PLLON bit)

Bit 30 **SPREADSEL**: Spread Select

This bit is set and cleared by software.

To write before to set CR[24]=PLLON bit.

0: Center spread

1: Down spread

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:13 **INCSTEP**: Incrementation step

These bits are set and cleared by software. To write before setting CR[24]=PLLON bit.  
Configuration input for modulation profile amplitude.

Bits 12:0 **MODPER**: Modulation period

These bits are set and cleared by software. To write before setting CR[24]=PLLON bit.  
Configuration input for modulation profile period.

### 6.3.23 RCC PLLI2S configuration register (RCC\_PLLI2SCFGR)

Address offset: 0x84

Reset value: 0x2400 3000

Access: no wait state, word, half-word and byte access.

This register is used to configure the PLLI2S clock outputs according to the formulas:

$$f_{(VCO \text{ clock})} = f_{(PLLI2S \text{ clock input})} \times (PLLI2SN / PLLM)$$

$$f_{(PLL I2S \text{ clock output})} = f_{(VCO \text{ clock})} / PLLI2SR$$

|              |              |              |              |              |              |              |              |              |              |          |    |    |    |    |    |

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLLI2SR**: PLLI2S division factor for I2S clocks

These bits are set and cleared by software to control the I2S clock frequency. These bits should be written only if the PLLI2S is disabled. The factor must be chosen in accordance with the prescaler values inside the I2S peripherals, to reach 0.3% error when using standard crystals and 0% error with audio crystals. For more information about I2S clock frequency and precision, refer to [Section 28.4.4: Clock generator](#) in the I2S chapter.

**Caution:** The I2Ss requires a frequency lower than or equal to 192 MHz to work correctly.

$\text{I2S clock frequency} = \text{VCO frequency} / \text{PLLR}$  with  $2 \leq \text{PLLR} \leq 7$

000: PLLR = 0, wrong configuration

001: PLLR = 1, wrong configuration

010: PLLR = 2

...

111: PLLR = 7

Bits 27:24 **PLLI2SQ**: PLLI2S division factor for SAI1 clock

These bits are set and cleared by software to control the SAI1 clock frequency. They should be written when the PLLI2S is disabled.

$\text{SAI1 clock frequency} = \text{VCO frequency} / \text{PLLI2SQ}$  with  $2 \leq \text{PLLI2SQ} \leq 15$

0000: PLLI2SQ = 0, wrong configuration

0001: PLLI2SQ = 1, wrong configuration

0010: PLLI2SQ = 2

0011: PLLI2SQ = 3

0100: PLLI2SQ = 4

0101: PLLI2SQ = 5

...

1111: PLLI2SQ = 15

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:6 **PLLI2SN**: PLLI2S multiplication factor for VCO

These bits are set and cleared by software to control the multiplication factor of the VCO.

These bits can be written only when PLLI2S is disabled. Only half-word and word accesses are allowed to write these bits.

**Caution:** The software has to set these bits correctly to ensure that the VCO output frequency is between 100 and 432 MHz.

VCO output frequency = VCO input frequency × PLLI2SN with  $50 \leq \text{PLLI2SN} \leq 432$

000000000: PLLI2SN = 0, wrong configuration

000000001: PLLI2SN = 1, wrong configuration

...

000110010: PLLI2SN = 50

...

001100011: PLLI2SN = 99

001100100: PLLI2SN = 100

001100101: PLLI2SN = 101

001100110: PLLI2SN = 102

...

110110000: PLLI2SN = 432

110110001: PLLI2SN = 433, wrong configuration

...

111111111: PLLI2SN = 511, wrong configuration

*Note: Multiplication factors ranging from 50 and 99 are possible for VCO input frequency higher than 1 MHz. However care must be taken that the minimum VCO output frequency respects the value specified above.*

Bits 5:0 Reserved, must be kept at reset value.

### 6.3.24 RCC PLL configuration register (RCC\_PLLSAICFGR)

Address offset: 0x88

Reset value: 0x2400 3000

Access: no wait state, word, half-word and byte access.

This register is used to configure the PLLSAI clock outputs according to the formulas:

- $f_{(VCO \text{ clock})} = f_{(PLLSAI \text{ clock input})} \times (PLLSAIN / PLLM)$
- $f_{(PLLSAI1 \text{ clock output})} = f_{(VCO \text{ clock})} / PLLSAIQ$
- $f_{(PLL \text{ LCD clock output})} = f_{(VCO \text{ clock})} / PLLSAIR$

|          |         |    |    |         |    |    |    |          |    |          |    |    |    |    |    |
|----------|---------|----|----|---------|----|----|----|----------|----|----------|----|----|----|----|----|
| 31       | 30      | 29 | 28 | 27      | 26 | 25 | 24 | 23       | 22 | 21       | 20 | 19 | 18 | 17 | 16 |
| Reserved | PLLSAIR |    |    | PLLSAIQ |    |    |    | Reserved |    |          |    |    |    |    |    |
|          | rw      | rw | rw | rw      | rw | rw | rw |          |    |          |    |    |    |    |    |
| 15       | 14      | 13 | 12 | 11      | 10 | 9  | 8  | 7        | 6  | 5        | 4  | 3  | 2  | 1  | 0  |
| Reserved | PLLSAIN |    |    |         |    |    |    |          |    | Reserved |    |    |    |    |    |
|          | rw      | rw | rw | rw      | rw | rw | rw | rw       | rw |          |    |    |    |    |    |

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLLSAIR**: PLLSAI division factor for LCD clock

Set and reset by software to control the LCD clock frequency.

These bits should be written when the PLLSAI is disabled.

LCD clock frequency = VCO frequency / PLLSAIR with  $2 \leq PLLSAIR \leq 7$

000: PLLSAIR = 0, wrong configuration

001: PLLSAIR = 1, wrong configuration

010: PLLSAIR = 2

...

111: PLLSAIR = 7

Bits 27:24 **PLLSAIQ**: PLLSAI division factor for SAI1 clock

Set and reset by software to control the frequency of SAI1 clock.

These bits should be written when the PLLSAI is disabled.

SAI1 clock frequency = VCO frequency / PLLSAIQ with  $2 \leq PLLSAIQ \leq 15$

0000: PLLSAIQ = 0, wrong configuration

0001: PLLSAIQ = 1, wrong configuration

...

0010: PLLSAIQ = 2

0011: PLLSAIQ = 3

0100: PLLSAIQ = 4

0101: PLLSAIQ = 5

...

1111: PLLSAIQ = 15

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:6 **PLLISAIN**: PLLSAI division factor for VCO

These bits are set and cleared by software to control the multiplication factor of the VCO.  
These bits can be written only when PLLSAI is disabled. Only half-word and word accesses are allowed to write these bits.

**Caution:** The software has to set these bits correctly to ensure that the VCO output frequency is between 100 and 432 MHz.

VCO output frequency = VCO input frequency × PLLISAIN with  $50 \leq \text{PLLISAIN} \leq 432$

00000000: PLLISAIN = 0, wrong configuration

00000001: PLLISAIN = 1, wrong configuration

...

000110010: PLLISAIN = 50

...

001100011: PLLISAIN = 99

001100100: PLLISAIN = 100

001100101: PLLISAIN = 101

001100110: PLLISAIN = 102

...

110110000: PLLISAIN = 432

110110001: PLLISAIN = 433, wrong configuration

...

111111111: PLLISAIN = 511, wrong configuration

*Note: Multiplication factors ranging from 50 and 99 are possible for VCO input frequency higher than 1 MHz. However care must be taken that the minimum VCO output frequency respects the value specified above.*

Bits 5:0 Reserved, must be kept at reset value

### 6.3.25 RCC Dedicated Clock Configuration Register (RCC\_DCKCFGR)

Address offset: 0x8C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

The RCC\_DCKCFGR register allows to configure the timer clock prescalers and the PLLSAI and PLLI2S output clock dividers for SAI1 and LTDC peripherals according to the following formula:

$$f_{(\text{PLLSAIDIVQ clock output})} = f_{(\text{PLLSAI\_Q})} / \text{PLLSAIDIVQ}$$

$$f_{(\text{PLLSAIDIVR clock output})} = f_{(\text{PLLSAI\_R})} / \text{PLLSAIDIVR}$$

$$f_{(\text{PLLI2SDIVQ clock output})} = f_{(\text{PLLI2S\_Q})} / \text{PLLI2SDIVQ}$$

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **TIMPRE**: Timers clocks prescalers selection

This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domain.

0: If the APB prescaler (PPRE1, PPRE2 in the RCC\_CFGR register) is configured to a division factor of 1,  $TIMxCLK = PCLKx$ . Otherwise, the timer clock frequencies are set to twice to the frequency of the APB domain to which the timers are connected:

$TIMxCLK = 2 \times PCLKx$ .

1: If the APB prescaler (PPRE1, PPRE2 in the RCC\_CFGR register) is configured to a division factor of 1, 2 or 4,  $TIMxCLK = HCLK$ . Otherwise, the timer clock frequencies are set to four times to the frequency of the APB domain to which the timers are connected:

$TIMxCLK = 4 \times PCLKx$ .

Bits 23:22 **SAI1BSRC**: SAI1-B clock source selection

These bits are set and cleared by software to control the SAI1-B clock frequency.

They should be written when the PLLSAI and PLLI2S are disabled.

00: SAI1-B clock frequency =  $f(PLLSAI\_Q) / PLLSAIDIVQ$

01: SAI1-B clock frequency =  $f(PLLI2S\_Q) / PLLI2SDIVQ$

10: SAI1-B clock frequency = Alternate function input frequency

11: wrong configuration

Bits 21:20 **SAI1ASRC**: SAI1-A clock source selection

These bits are set and cleared by software to control the SAI1-A clock frequency.

They should be written when the PLLSAI and PLLI2S are disabled.

00: SAI1-A clock frequency =  $f(PLLSAI\_Q) / PLLSAIDIVQ$

01: SAI1-A clock frequency =  $f(PLLI2S\_Q) / PLLI2SDIVQ$

10: SAI1-A clock frequency = Alternate function input frequency

11: wrong configuration

Bits 19: 18 Reserved, must be kept at reset value.

Bits 17:16 **PLLSAIDIVR**: division factor for LCD\_CLK

These bits are set and cleared by software to control the frequency of LCD\_CLK.

They should be written only if PLLSAI is disabled.

$LCD\_CLK \text{ frequency} = f(PLLSAI\_R) / PLLSAIDIVR$  with  $2 \leq PLLSAIDIVR \leq 16$

00:  $PLLSAIDIVR = /2$

01:  $PLLSAIDIVR = /4$

10:  $PLLSAIDIVR = /8$

11:  $PLLSAIDIVR = /16$

Bits 15: 13 Reserved, must be kept at reset value.

Bits 12:8 **PLLSAIDIVQ**: PLLSAI division factor for SAI1 clock

These bits are set and reset by software to control the SAI1 clock frequency.

They should be written only if PLLSAI is disabled.

SAI1 clock frequency =  $f(\text{PLLSAI\_Q}) / \text{PLLSAIDIVQ}$  with  $1 \leq \text{PLLSAIDIVQ} \leq 31$

00000: PLLSAIDIVQ = /1

00001: PLLSAIDIVQ = /2

00010: PLLSAIDIVQ = /3

00011: PLLSAIDIVQ = /4

00100: PLLSAIDIVQ = /5

...

11111: PLLSAIDIVQ = /32

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **PLLI2SDIVQ**: PLLI2S division factor for SAI1 clock

These bits are set and reset by software to control the SAI1 clock frequency.

They should be written only if PLLI2S is disabled.

SAI1 clock frequency =  $f(\text{PLLI2S\_Q}) / \text{PLLI2SDIVQ}$  with  $1 \leq \text{PLLI2SDIVQ} \leq 31$

00000: PLLI2SDIVQ = /1

00001: PLLI2SDIVQ = /2

00010: PLLI2SDIVQ = /3

00011: PLLI2SDIVQ = /4

00100: PLLI2SDIVQ = /5

...

11111: PLLI2SDIVQ = /32

### 6.3.26 RCC register map

Table 33 gives the register map and reset values.

Table 33. RCC register map and reset values for STM32F42xxx and STM32F43xxx

| Addr. offset | Register name | 31       | 30          | 29        | 28          | 27         | 26         | 25       | 24       | 23       | 22      | 21         | 20           | 19       | 18        | 17       | 16       | 15       | 14         | 13          | 12          | 11       | 10       | 9         | 8        | 7         | 6         | 5          | 4          | 3         | 2        | 1        | 0        |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |          |

## 7 Reset and clock control for STM32F405xx/07xx and STM32F415xx/17xx(RCC)

### 7.1 Reset

There are three types of reset, defined as system Reset, power Reset and backup domain Reset.

#### 7.1.1 System reset

A system reset sets all registers to their reset values except the reset flags in the clock controller CSR register and the registers in the Backup domain (see [Figure 4](#)).

A system reset is generated when one of the following events occurs:

1. A low level on the NRST pin (external reset)
2. Window watchdog end of count condition (WWDG reset)
3. Independent watchdog end of count condition (IWDG reset)
4. A software reset (SW reset) (see [Software reset](#))
5. Low-power management reset (see [Low-power management reset](#))

#### Software reset

The reset source can be identified by checking the reset flags in the [RCC clock control & status register \(RCC\\_CSR\)](#).

The SYSRESETREQ bit in Cortex®-M4 with FPU Application Interrupt and Reset Control Register must be set to force a software reset on the device. Refer to the Cortex®-M4 with FPU technical reference manual for more details.

### Low-power management reset

There are two ways of generating a low-power management reset:

1. Reset generated when entering the Standby mode:  
This type of reset is enabled by resetting the nRST\_STDBY bit in the user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering the Standby mode.
2. Reset when entering the Stop mode:  
This type of reset is enabled by resetting the nRST\_STOP bit in the user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering the Stop mode.

### 7.1.2 Power reset

A power reset is generated when one of the following events occurs:

1. Power-on/power-down reset (POR/PDR reset) or brownout (BOR) reset
2. When exiting the Standby mode

A power reset sets all registers to their reset values except the Backup domain (see [Figure 4](#))

These sources act on the NRST pin and it is always kept low during the delay phase. The RESET service routine vector is fixed at address 0x0000\_0004 in the memory map.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20  $\mu$ s for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

**Figure 20. Simplified diagram of the reset circuit**

The Backup domain has two specific resets that affect only the Backup domain (see [Figure 4](#)).

### 7.1.3 Backup domain reset

The backup domain reset sets all RTC registers and the RCC\_BDCR register to their reset values. The BKPSRAM is not affected by this reset. The only way of resetting the BKPSRAM is through the Flash interface by requesting a protection level change from 1 to 0.

A backup domain reset is generated when one of the following events occurs:

1. Software reset, triggered by setting the BDRST bit in the [RCC Backup domain control register \(RCC\\_BDCR\)](#).
2.  $V_{DD}$  or  $V_{BAT}$  power on, if both supplies have previously been powered off.

## 7.2 Clocks

Three different clock sources can be used to drive the system clock (SYSCLK):

- HSI oscillator clock
- HSE oscillator clock
- Main PLL (PLL) clock

The devices have the two following secondary clock sources:

- 32 kHz low-speed internal RC (LSI RC) which drives the independent watchdog and, optionally, the RTC used for Auto-wakeup from the Stop/Standby mode.
- 32.768 kHz low-speed external crystal (LSE crystal) which optionally drives the RTC clock (RTCCLK)

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Figure 21. Clock tree

- For full details about the internal and external clock source characteristics, refer to the Electrical characteristics section in the device datasheet.

The clock controller provides a high degree of flexibility to the application in the choice of the external crystal or the oscillator to run the core and peripherals at the highest frequency and, guarantee the appropriate frequency for peripherals that need a specific clock like Ethernet, USB OTG FS and HS, I2S and SDIO.

Several prescalers are used to configure the AHB frequency, the high-speed APB (APB2) and the low-speed APB (APB1) domains. The maximum frequency of the AHB domain is 168 MHz. The maximum allowed frequency of the high-speed APB2 domain is 84 MHz. The maximum allowed frequency of the low-speed APB1 domain is 42 MHz

All peripheral clocks are derived from the system clock (SYSCLK) except for:

- The USB OTG FS clock (48 MHz), the random analog generator (RNG) clock ( $\leq 48$  MHz) and the SDIO clock ( $\leq 48$  MHz) which are coming from a specific output of PLL (PLL48CLK)
- The I2S clock  
To achieve high-quality audio performance, the I2S clock can be derived either from a specific PLL (PLL12S) or from an external clock mapped on the I2S\_CKIN pin. For more information about I2S clock frequency and precision, refer to [Section 28.4.4: Clock generator](#).
- The USB OTG HS (60 MHz) clock which is provided from the external PHY
- The Ethernet MAC clocks (TX, RX and RMII) which are provided from the external PHY. For further information on the Ethernet configuration, please refer to [Section 33.4.4: MII/RMII selection](#) in the Ethernet peripheral description. When the Ethernet is used, the AHB clock frequency must be at least 25 MHz.

The RCC feeds the external clock of the Cortex System Timer (SysTick) with the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or with the Cortex clock (HCLK), configurable in the SysTick control and status register.

The timer clock frequencies are automatically set by hardware. There are two cases:

1. If the APB prescaler is 1, the timer clock frequencies are set to the same frequency as that of the APB domain to which the timers are connected.
2. Otherwise, they are set to twice ( $\times 2$ ) the frequency of the APB domain to which the timers are connected.

FCLK acts as Cortex<sup>®</sup>-M4 with FPU free-running clock. For more details, refer to the Cortex<sup>®</sup>-M4 with FPU technical reference manual.

## 7.2.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE external user clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

Figure 22. HSE/ LSE clock sources

### External source (HSE bypass)

In this mode, an external clock source must be provided. You select this mode by setting the HSEBYP and HSEON bits in the [RCC clock control register \(RCC\\_CR\)](#). The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC\_IN pin while the OSC\_OUT pin should be left HI-Z. See [Figure 22](#).

### External crystal/ceramic resonator (HSE crystal)

The HSE has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in [Figure 22](#). Refer to the electrical characteristics section of the *datasheet* for more details.

The HSERDY flag in the [RCC clock control register \(RCC\\_CR\)](#) indicates if the high-speed external oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the [RCC clock interrupt register \(RCC\\_CIR\)](#).

The HSE Crystal can be switched on and off using the HSEON bit in the [RCC clock control register \(RCC\\_CR\)](#).

## 7.2.2 HSI clock

The HSI clock signal is generated from an internal 16 MHz RC oscillator and can be used directly as a system clock, or used as PLL input.

The HSI RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator however, even with calibration the frequency is less accurate than an external crystal oscillator or ceramic resonator.

## Calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1% accuracy at  $T_A = 25\text{ }^{\circ}\text{C}$ .

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the [RCC clock control register \(RCC\\_CR\)](#).

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. You can trim the HSI frequency in the application using the HSITRIM[4:0] bits in the [RCC clock control register \(RCC\\_CR\)](#).

The HSIRDY flag in the [RCC clock control register \(RCC\\_CR\)](#) indicates if the HSI RC is stable or not. At startup, the HSI RC output clock is not released until this bit is set by hardware.

The HSI RC can be switched on and off using the HSION bit in the [RCC clock control register \(RCC\\_CR\)](#).

The HSI signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to [Section 7.2.7: Clock security system \(CSS\) on page 220](#).

## 7.2.3 PLL configuration

The STM32F4xx devices feature two PLLs:

- A main PLL (PLL) clocked by the HSE or HSI oscillator and featuring two different output clocks:
  - The first output is used to generate the high speed system clock (up to 168 MHz)
  - The second output is used to generate the clock for the USB OTG FS (48 MHz), the random analog generator ( $\leq 48\text{ MHz}$ ) and the SDIO ( $\leq 48\text{ MHz}$ ).
- A dedicated PLL (PLLI2S) used to generate an accurate clock to achieve high-quality audio performance on the I2S interface.

Since the main-PLL configuration parameters cannot be changed once PLL is enabled, it is recommended to configure PLL before enabling it (selection of the HSI or HSE oscillator as PLL clock source, and configuration of division factors M, N, P, and Q).

The PLLI2S uses the same input clock as PLL (PLLM[5:0] and PLLSRC bits are common to both PLLs). However, the PLLI2S has dedicated enable/disable and division factors (N and R) configuration bits. Once the PLLI2S is enabled, the configuration parameters cannot be changed.

The two PLLs are disabled by hardware when entering Stop and Standby modes, or when an HSE failure occurs when HSE or PLL (clocked by HSE) are used as system clock. [RCC PLL configuration register \(RCC\\_PLLCFGR\)](#) and [RCC clock configuration register \(RCC\\_CFGR\)](#) can be used to configure PLL and PLLI2S, respectively.

## 7.2.4 LSE clock

The LSE clock is generated from a 32.768 kHz low-speed external crystal or ceramic resonator. It has the advantage providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE oscillator is switched on and off using the LSEON bit in [RCC Backup domain control register \(RCC\\_BDCR\)](#).

The LSERDY flag in the *RCC Backup domain control register (RCC\_BDCR)* indicates if the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock interrupt register (RCC\_CIR)*.

### External source (LSE bypass)

In this mode, an external clock source must be provided. It must have a frequency up to 1 MHz. You select this mode by setting the LSEBYP and LSEON bits in the *RCC Backup domain control register (RCC\_BDCR)*. The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC32\_IN pin while the OSC32\_OUT pin should be left HI-Z. See *Figure 22*.

## 7.2.5 LSI clock

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG) and Auto-wakeup unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheets.

The LSI RC can be switched on and off using the LSION bit in the *RCC clock control & status register (RCC\_CSR)*.

The LSIRDY flag in the *RCC clock control & status register (RCC\_CSR)* indicates if the low-speed internal oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock interrupt register (RCC\_CIR)*.

## 7.2.6 System clock (SYSCLK) selection

After a system reset, the HSI oscillator is selected as the system clock. When a clock source is used directly or through PLL as the system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready. Status bits in the *RCC clock control register (RCC\_CR)* indicate which clock(s) is (are) ready and which clock is currently used as the system clock.

## 7.2.7 Clock security system (CSS)

The clock security system can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, this oscillator is automatically disabled, a clock failure event is sent to the break inputs of advanced-control timers TIM1 and TIM8, and an interrupt is generated to inform the software about the failure (clock security system interrupt CSSI), allowing the MCU to perform rescue operations. The CSSI is linked to the Cortex®-M4 with FPU NMI (non-maskable interrupt) exception vector.

*Note:* When the CSS is enabled, if the HSE clock happens to fail, the CSS generates an interrupt, which causes the automatic generation of an NMI. The NMI is executed indefinitely unless the CSS interrupt pending bit is cleared. As a consequence, the application has to clear the CSS interrupt in the NMI ISR by setting the CSSC bit in the Clock interrupt register (RCC\_CIR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly meaning that it is directly used as PLL input clock, and that PLL clock is the system clock) and a failure is detected, then the system clock switches to the HSI oscillator and the HSE oscillator is disabled.

If the HSE oscillator clock was the clock source of PLL used as the system clock when the failure occurred, PLL is also disabled. In this case, if the PLLI2S was enabled, it is also disabled when the HSE fails.

## 7.2.8 RTC/AWU clock

Once the RTCCLK clock source has been selected, the only possible way of modifying the selection is to reset the power domain.

The RTCCLK clock source can be either the HSE 1 MHz (HSE divided by a programmable prescaler), the LSE or the LSI clock. This is selected by programming the RTCSEL[1:0] bits in the [RCC Backup domain control register \(RCC\\_BDCR\)](#) and the RTCPRE[4:0] bits in [RCC clock configuration register \(RCC\\_CFGR\)](#). This selection cannot be modified without resetting the Backup domain.

If the LSE is selected as the RTC clock, the RTC operates normally if the backup or the system supply disappears. If the LSI is selected as the AWU clock, the AWU state is not guaranteed if the system supply disappears. If the HSE oscillator divided by a value between 2 and 31 is used as the RTC clock, the RTC state is not guaranteed if the backup or the system supply disappears.

The LSE clock is in the Backup domain, whereas the HSE and LSI clocks are not. As a consequence:

- If LSE is selected as the RTC clock:
  - The RTC continues to work even if the  $V_{DD}$  supply is switched off, provided the  $V_{BAT}$  supply is maintained.
- If LSI is selected as the Auto-wakeup unit (AWU) clock:
  - The AWU state is not guaranteed if the  $V_{DD}$  supply is powered off. Refer to [Section 7.2.5: LSI clock on page 220](#) for more details on LSI calibration.
- If the HSE clock is used as the RTC clock:
  - The RTC state is not guaranteed if the  $V_{DD}$  supply is powered off or if the internal voltage regulator is powered off (removing power from the 1.2 V domain).

**Note:** *To read the RTC calendar register when the APB1 clock frequency is less than seven times the RTC clock frequency ( $f_{APB1} < 7 \times f_{RTCCLK}$ ), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC\_TR gives the same result than the first one. Otherwise a third read access must be performed.*

## 7.2.9 Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced ON and cannot be disabled. After the LSI oscillator temporization, the clock is provided to the IWDG.

### 7.2.10 Clock-out capability

Two microcontroller clock output (MCO) pins are available:

- MCO1

You can output four different clock sources onto the MCO1 pin (PA8) using the configurable prescaler (from 1 to 5):

- HSI clock
- LSE clock
- HSE clock
- PLL clock

The desired clock source is selected using the MCO1PRE[2:0] and MCO1[1:0] bits in the [RCC clock configuration register \(RCC\\_CFGR\)](#).

- MCO2

You can output four different clock sources onto the MCO2 pin (PC9) using the configurable prescaler (from 1 to 5):

- HSE clock
- PLL clock
- System clock (SYSCLK)
- PLLI2S clock

The desired clock source is selected using the MCO2PRE[2:0] and MCO2 bits in the [RCC clock configuration register \(RCC\\_CFGR\)](#).

For the different MCO pins, the corresponding GPIO port has to be programmed in alternate function mode.

The selected clock to output onto MCO must not exceed 100 MHz (the maximum I/O speed).

### 7.2.11 Internal/external clock measurement using TIM5/TIM11

It is possible to indirectly measure the frequencies of all on-board clock source generators by means of the input capture of TIM5 channel4 and TIM11 channel1 as shown in [Figure 23](#) and [Figure 24](#).

#### Internal/external clock measurement using TIM5 channel4

TIM5 has an input multiplexer which allows choosing whether the input capture is triggered by the I/O or by an internal clock. This selection is performed through the TI4\_RMP [1:0] bits in the TIM5\_OR register.

The primary purpose of having the LSE connected to the channel4 input capture is to be able to precisely measure the HSI (this requires to have the HSI used as the system clock source). The number of HSI clock counts between consecutive edges of the LSE signal provides a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

The HSI oscillator has dedicated, user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio): the precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio, the better the measurement.

It is also possible to measure the LSI frequency: this is useful for applications that do not have a crystal. The ultralow-power LSI oscillator has a large manufacturing process deviation: by measuring it versus the HSI clock source, it is possible to determine its frequency with the precision of the HSI. The measured value can be used to have more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy.

Use the following procedure to measure the LSI frequency:

1. Enable the TIM5 timer and configure channel4 in Input capture mode.
2. Set the TI4\_RMP bits in the TIM5\_OR register to 0x01 to connect the LSI clock internally to TIM5 channel4 input capture for calibration purposes.
3. Measure the LSI clock frequency using the TIM5 capture/compare 4 event or interrupt.
4. Use the measured LSI frequency to update the prescaler of the RTC depending on the desired time base and/or to compute the IWDG timeout.

**Figure 23. Frequency measurement with TIM5 in Input capture mode**

#### Internal/external clock measurement using TIM11 channel1

TIM11 has an input multiplexer which allows choosing whether the input capture is triggered by the I/O or by an internal clock. This selection is performed through TI1\_RMP [1:0] bits in the TIM11\_OR register. The HSE\_RTC clock (HSE divided by a programmable prescaler) is connected to channel 1 input capture to have a rough indication of the external crystal frequency. This requires that the HSI is the system clock source. This can be useful for instance to ensure compliance with the IEC 60730/IEC 61335 standards which require to be able to determine harmonic or subharmonic frequencies (–50/+100% deviations).

**Figure 24. Frequency measurement with TIM11 in Input capture mode**

## 7.3 RCC registers

Refer to [Section 1.1: List of abbreviations for registers](#) for a list of abbreviations used in register descriptions.

### 7.3.1 RCC clock control register (RCC\_CR)

Address offset: 0x00

Reset value: 0x0000 XX83 where X is undefined.

Access: no wait state, word, half-word and byte access

|             |    |    |    |               |              |            |           |              |    |    |    |           |            |            |           |
|-------------|----|----|----|---------------|--------------|------------|-----------|--------------|----|----|----|-----------|------------|------------|-----------|
| 31          | 30 | 29 | 28 | 27            | 26           | 25         | 24        | 23           | 22 | 21 | 20 | 19        | 18         | 17         | 16        |
| Reserved    |    |    |    | PLLI2S<br>RDY | PLLI2S<br>ON | PLL<br>RDY | PLL<br>ON | Reserved     |    |    |    | CSS<br>ON | HSE<br>BYP | HSE<br>RDY | HSE<br>ON |
|             |    |    |    | r             | rw           | r          | rw        |              |    |    |    | rw        | rw         | r          | rw        |
| 15          | 14 | 13 | 12 | 11            | 10           | 9          | 8         | 7            | 6  | 5  | 4  | 3         | 2          | 1          | 0         |
| HSICAL[7:0] |    |    |    |               |              |            |           | HSITRIM[4:0] |    |    |    |           | Res.       | HSI<br>RDY | HSION     |
| r           | r  | r  | r  | r             | r            | r          | r         | rw           | rw | rw | rw | rw        |            | r          | rw        |

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **PLLI2SRDY**: PLLI2S clock ready flag

Set by hardware to indicate that the PLLI2S is locked.

0: PLLI2S unlocked

1: PLLI2S locked

Bit 26 **PLLI2SON**: PLLI2S enable

Set and cleared by software to enable PLLI2S.

Cleared by hardware when entering Stop or Standby mode.

0: PLLI2S OFF

1: PLLI2S ON

Bit 25 **PLLRDY**: Main PLL (PLL) clock ready flag

Set by hardware to indicate that PLL is locked.

0: PLL unlocked

1: PLL locked

Bit 24 **PLLON**: Main PLL (PLL) enable

Set and cleared by software to enable PLL.

Cleared by hardware when entering Stop or Standby mode. This bit cannot be reset if PLL clock is used as the system clock.

0: PLL OFF

1: PLL ON

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CSSON**: Clock security system enable

Set and cleared by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if an oscillator failure is detected.

0: Clock security system OFF (Clock detector OFF)

1: Clock security system ON (Clock detector ON if HSE oscillator is stable, OFF if not)

**Bit 18 HSEBYP:** HSE clock bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit, to be used by the device.  
The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE oscillator not bypassed

1: HSE oscillator bypassed with an external clock

**Bit 17 HSERDY:** HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable. After the HSEON bit is cleared, HSERDY goes low after 6 HSE oscillator clock cycles.

0: HSE oscillator not ready

1: HSE oscillator ready

**Bit 16 HSEON:** HSE clock enable

Set and cleared by software.

Cleared by hardware to stop the HSE oscillator when entering Stop or Standby mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.

0: HSE oscillator OFF

1: HSE oscillator ON

**Bits 15:8 HSICAL[7:0]:** Internal high-speed clock calibration

These bits are initialized automatically at startup.

**Bits 7:3 HSITRIM[4:0]:** Internal high-speed clock trimming

These bits provide an additional user-programmable trimming value that is added to the HSICAL[7:0] bits. It can be programmed to adjust to variations in voltage and temperature that influence the frequency of the internal HSI RC.

**Bit 2** Reserved, must be kept at reset value.**Bit 1 HSIRDY:** Internal high-speed clock ready flag

Set by hardware to indicate that the HSI oscillator is stable. After the HSION bit is cleared, HSIRDY goes low after 6 HSI clock cycles.

0: HSI oscillator not ready

1: HSI oscillator ready

**Bit 0 HSION:** Internal high-speed clock enable

Set and cleared by software.

Set by hardware to force the HSI oscillator ON when leaving the Stop or Standby mode or in case of a failure of the HSE oscillator used directly or indirectly as the system clock. This bit cannot be cleared if the HSI is used directly or indirectly as the system clock.

0: HSI oscillator OFF

1: HSI oscillator ON

### 7.3.2 RCC PLL configuration register (RCC\_PLLCFGR)

Address offset: 0x04

Reset value: 0x2400 3010

Access: no wait state, word, half-word and byte access.

This register is used to configure the PLL clock outputs according to the formulas:

- $f_{(VCO \text{ clock})} = f_{(PLL \text{ clock input})} \times (PLL_N / PLL_M)$
- $f_{(PLL \text{ general clock output})} = f_{(VCO \text{ clock})} / PLL_P$
- $f_{(USB \text{ OTG FS, SDIO, RNG clock output})} = f_{(VCO \text{ clock})} / PLL_Q$

|          |       |    |    |       |       |       |       |          |        |          |       |       |       |       |       |
|----------|-------|----|----|-------|-------|-------|-------|----------|--------|----------|-------|-------|-------|-------|-------|
| 31       | 30    | 29 | 28 | 27    | 26    | 25    | 24    | 23       | 22     | 21       | 20    | 19    | 18    | 17    | 16    |
| Reserved |       |    |    | PLLQ3 | PLLQ2 | PLLQ1 | PLLQ0 | Reserved | PLLSRC | Reserved |       |       |       | PLLP1 | PLLP0 |
|          |       |    |    | rw    | rw    | rw    | rw    |          | rw     |          |       |       |       | rw    | rw    |
| 15       | 14    | 13 | 12 | 11    | 10    | 9     | 8     | 7        | 6      | 5        | 4     | 3     | 2     | 1     | 0     |
| Reserved | PLL_N |    |    |       |       |       |       |          |        | PLLM5    | PLLM4 | PLLM3 | PLLM2 | PLLM1 | PLLM0 |
|          | rw    | rw | rw | rw    | rw    | rw    | rw    | rw       | rw     | rw       | rw    | rw    | rw    | rw    | rw    |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **PLLQ**: Main PLL (PLL) division factor for USB OTG FS, SDIO and random number generator clocks

Set and cleared by software to control the frequency of USB OTG FS clock, the random number generator clock and the SDIO clock. These bits should be written only if PLL is disabled.

**Caution:** The USB OTG FS requires a 48 MHz clock to work correctly. The SDIO and the random number generator need a frequency lower than or equal to 48 MHz to work correctly.

USB OTG FS clock frequency = VCO frequency / PLLQ with  $2 \leq PLLQ \leq 15$

0000: PLLQ = 0, wrong configuration

0001: PLLQ = 1, wrong configuration

0010: PLLQ = 2

0011: PLLQ = 3

0100: PLLQ = 4

...

1111: PLLQ = 15

Bit 23 Reserved, must be kept at reset value.

Bit 22 **PLLSRC**: Main PLL(PLL) and audio PLL (PLLI2S) entry clock source

Set and cleared by software to select PLL and PLLI2S clock source. This bit can be written only when PLL and PLLI2S are disabled.

0: HSI clock selected as PLL and PLLI2S clock entry

1: HSE oscillator clock selected as PLL and PLLI2S clock entry

Bits 21:18 Reserved, must be kept at reset value.

Bits 17:16 **PLL**: Main PLL (PLL) division factor for main system clock

Set and cleared by software to control the frequency of the general PLL output clock. These bits can be written only if PLL is disabled.

**Caution:** The software has to set these bits correctly not to exceed 168 MHz on this domain.

PLL output clock frequency = VCO frequency / PLLP with PLLP = 2, 4, 6, or 8

00: PLLP = 2

01: PLLP = 4

10: PLLP = 6

11: PLLP = 8

Bits 14:6 **PLLN**: Main PLL (PLL) multiplication factor for VCO

Set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when PLL is disabled. Only half-word and word accesses are allowed to write these bits.

**Caution:** The software has to set these bits correctly to ensure that the VCO output frequency is between 100 and 432 MHz.

VCO output frequency = VCO input frequency × PLLN with  $50 \leq \text{PLLN} \leq 432$

00000000: PLLN = 0, wrong configuration

00000001: PLLN = 1, wrong configuration

...

000110010: PLLN = 50

...

001100011: PLLN = 99

001100100: PLLN = 100

...

110110000: PLLN = 432

110110001: PLLN = 433, wrong configuration

...

111111111: PLLN = 511, wrong configuration

*Note: Multiplication factors ranging from 50 and 99 are possible for VCO input frequency higher than 1 MHz. However care must be taken that the minimum VCO output frequency respects the value specified above.*

Bits 5:0 **PLLM**: Division factor for the main PLL (PLL) and audio PLL (PLLI2S) input clock

Set and cleared by software to divide the PLL and PLLI2S input clock before the VCO. These bits can be written only when the PLL and PLLI2S are disabled.

**Caution:** The software has to set these bits correctly to ensure that the VCO input frequency ranges from 1 to 2 MHz. It is recommended to select a frequency of 2 MHz to limit PLL jitter.

VCO input frequency = PLL input clock frequency / PLLM with  $2 \leq \text{PLLM} \leq 63$

000000: PLLM = 0, wrong configuration

000001: PLLM = 1, wrong configuration

000010: PLLM = 2

000011: PLLM = 3

000100: PLLM = 4

...

111110: PLLM = 62

111111: PLLM = 63

### 7.3.3 RCC clock configuration register (RCC\_CFGR)

Address offset: 0x08

Reset value: 0x0000 0000

Access:  $0 \leq \text{wait state} \leq 2$ , word, half-word and byte access

1 or 2 wait states inserted only if the access occurs during a clock source switch.

|            |    |               |            |    |               |          |    |            |      |    |             |      |      |     |     |
|------------|----|---------------|------------|----|---------------|----------|----|------------|------|----|-------------|------|------|-----|-----|
| 31         | 30 | 29            | 28         | 27 | 26            | 25       | 24 | 23         | 22   | 21 | 20          | 19   | 18   | 17  | 16  |
| MCO2       |    | MCO2 PRE[2:0] |            |    | MCO1 PRE[2:0] |          |    | I2SSC<br>R | MCO1 |    | RTCPRE[4:0] |      |      |     |     |
| rw         |    | rw            | rw         | rw | rw            | rw       | rw | rw         | rw   |    | rw          | rw   | rw   | rw  | rw  |
| 15         | 14 | 13            | 12         | 11 | 10            | 9        | 8  | 7          | 6    | 5  | 4           | 3    | 2    | 1   | 0   |
| PPRE2[2:0] |    |               | PPRE1[2:0] |    |               | Reserved |    | HPRE[3:0]  |      |    |             | SWS1 | SWS0 | SW1 | SW0 |
| rw         | rw | rw            | rw         | rw | rw            |          |    | rw         | rw   | rw | rw          | r    | r    | rw  | rw  |

Bits 31:30 **MCO2[1:0]**: Microcontroller clock output 2

Set and cleared by software. Clock source selection may generate glitches on MCO2. It is highly recommended to configure these bits only after reset before enabling the external oscillators and the PLLs.

00: System clock (SYSCLK) selected

01: PLLI2S clock selected

10: HSE oscillator clock selected

11: PLL clock selected

Bits 27:29 **MCO2PRE**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset before enabling the external oscillators and the PLLs.

0xx: no division

100: division by 2

101: division by 3

110: division by 4

111: division by 5

Bits 24:26 **MCO1PRE**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset before enabling the external oscillators and the PLL.

0xx: no division

100: division by 2

101: division by 3

110: division by 4

111: division by 5

Bit 23 **I2SSRC**: I2S clock selection

Set and cleared by software. This bit allows to select the I2S clock source between the PLLI2S clock and the external clock. It is highly recommended to change this bit only after reset and before enabling the I2S module.

0: PLLI2S clock used as I2S clock source

1: External clock mapped on the I2S\_CKIN pin used as I2S clock source

Bits 22:21 **MCO1**: Microcontroller clock output 1

Set and cleared by software. Clock source selection may generate glitches on MCO1. It is highly recommended to configure these bits only after reset before enabling the external oscillators and PLL.

00: HSI clock selected

01: LSE oscillator selected

10: HSE oscillator clock selected

11: PLL clock selected

Bits 20:16 **RTCPRE**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE clock input clock to generate a 1 MHz clock for RTC.

**Caution:** The software has to set these bits correctly to ensure that the clock supplied to the RTC is 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

00000: no clock

00001: no clock

00010: HSE/2

00011: HSE/3

00100: HSE/4

...

11110: HSE/30

11111: HSE/31

Bits 15:13 **PPRE2**: APB high-speed prescaler (APB2)

Set and cleared by software to control APB high-speed clock division factor.

**Caution:** The software has to set these bits correctly not to exceed 84 MHz on this domain. The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after PPRE2 write.

0xx: AHB clock not divided

100: AHB clock divided by 2

101: AHB clock divided by 4

110: AHB clock divided by 8

111: AHB clock divided by 16

Bits 12:10 **PPRE1**: APB Low speed prescaler (APB1)

Set and cleared by software to control APB low-speed clock division factor.

**Caution:** The software has to set these bits correctly not to exceed 42 MHz on this domain. The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after PPRE1 write.

0xx: AHB clock not divided

100: AHB clock divided by 2

101: AHB clock divided by 4

110: AHB clock divided by 8

111: AHB clock divided by 16

Bits 9:8 Reserved, must be kept at reset value.

Bits 7:4 **HPRE**: AHB prescaler

Set and cleared by software to control AHB clock division factor.

**Caution:** The clocks are divided with the new prescaler factor from 1 to 16 AHB cycles after HPRE write.

**Caution:** The AHB clock frequency must be at least 25 MHz when the Ethernet is used.

0xxx: system clock not divided  
 1000: system clock divided by 2  
 1001: system clock divided by 4  
 1010: system clock divided by 8  
 1011: system clock divided by 16  
 1100: system clock divided by 64  
 1101: system clock divided by 128  
 1110: system clock divided by 256  
 1111: system clock divided by 512

Bits 3:2 **SWS**: System clock switch status

Set and cleared by hardware to indicate which clock source is used as the system clock.

00: HSI oscillator used as the system clock  
 01: HSE oscillator used as the system clock  
 10: PLL used as the system clock  
 11: not applicable

Bits 1:0 **SW**: System clock switch

Set and cleared by software to select the system clock source.

Set by hardware to force the HSI selection when leaving the Stop or Standby mode or in case of failure of the HSE oscillator used directly or indirectly as the system clock.

00: HSI oscillator selected as system clock  
 01: HSE oscillator selected as system clock  
 10: PLL selected as system clock  
 11: not allowed

### 7.3.4 RCC clock interrupt register (RCC\_CIR)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|          |    |                 |              |              |              |              |              |      |              |                |             |             |             |             |             |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **CSSC**: Clock security system interrupt clear

This bit is set by software to clear the CSSF flag.

0: No effect

1: Clear CSSF flag

Bits 22 Reserved, must be kept at reset value.

Bit 21 **PLLI2SRDYC**: PLLI2S ready interrupt clear

This bit is set by software to clear the PLLI2SRDYF flag.

0: No effect

1: PLLI2SRDYF cleared

Bit 20 **PLLRDYC**: Main PLL(PLL) ready interrupt clear

This bit is set by software to clear the PLLRDYF flag.

0: No effect

1: PLLRDYF cleared

Bit 19 **HSERDYC**: HSE ready interrupt clear

This bit is set by software to clear the HSERDYF flag.

0: No effect

1: HSERDYF cleared

Bit 18 **HSIRDYC**: HSI ready interrupt clear

This bit is set software to clear the HSIRDYF flag.

0: No effect

1: HSIRDYF cleared

Bit 17 **LSERDYC**: LSE ready interrupt clear

This bit is set by software to clear the LSERDYF flag.

0: No effect

1: LSERDYF cleared

Bit 16 **LSIRDYC**: LSI ready interrupt clear

This bit is set by software to clear the LSIRDYF flag.

0: No effect

1: LSIRDYF cleared

Bits 15:12 Reserved, must be kept at reset value.

Bit 13 **PLLI2SRDYIE**: PLLI2S ready interrupt enable

Set and cleared by software to enable/disable interrupt caused by PLLI2S lock.

0: PLLI2S lock interrupt disabled

1: PLLI2S lock interrupt enabled

Bit 12 **PLLRDYIE**: Main PLL (PLL) ready interrupt enable

Set and cleared by software to enable/disable interrupt caused by PLL lock.

0: PLL lock interrupt disabled

1: PLL lock interrupt enabled

Bit 11 **HSERDYIE**: HSE ready interrupt enable

Set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.

0: HSE ready interrupt disabled

1: HSE ready interrupt enabled

- Bit 10 **HSIRDYIE**: HSI ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by the HSI oscillator stabilization.  
0: HSI ready interrupt disabled  
1: HSI ready interrupt enabled
- Bit 9 **LSERDYIE**: LSE ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.  
0: LSE ready interrupt disabled  
1: LSE ready interrupt enabled
- Bit 8 **LSIRDYIE**: LSI ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by LSI oscillator stabilization.  
0: LSI ready interrupt disabled  
1: LSI ready interrupt enabled
- Bit 7 **CSSF**: Clock security system interrupt flag  
Set by hardware when a failure is detected in the HSE oscillator.  
Cleared by software setting the CSSC bit.  
0: No clock security interrupt caused by HSE clock failure  
1: Clock security interrupt caused by HSE clock failure
- Bits 6 Reserved, must be kept at reset value.
- Bit 5 **PLLI2SRDYF**: PLLI2S ready interrupt flag  
Set by hardware when the PLLI2S locks and PLLI2SRDYDIE is set.  
Cleared by software setting the PLLI2SDYC bit.  
0: No clock ready interrupt caused by PLLI2S lock  
1: Clock ready interrupt caused by PLLI2S lock
- Bit 4 **PLLRDYF**: Main PLL (PLL) ready interrupt flag  
Set by hardware when PLL locks and PLLRDYDIE is set.  
Cleared by software setting the PLLRDYC bit.  
0: No clock ready interrupt caused by PLL lock  
1: Clock ready interrupt caused by PLL lock
- Bit 3 **HSERDYF**: HSE ready interrupt flag  
Set by hardware when External High Speed clock becomes stable and HSERDYDIE is set.  
Cleared by software setting the HSERDYC bit.  
0: No clock ready interrupt caused by the HSE oscillator  
1: Clock ready interrupt caused by the HSE oscillator

**Bit 2 HSIRDYF:** HSI ready interrupt flag

Set by hardware when the Internal High Speed clock becomes stable and HSIRDYDIE is set.

Cleared by software setting the HSIRDYC bit.

0: No clock ready interrupt caused by the HSI oscillator

1: Clock ready interrupt caused by the HSI oscillator

**Bit 1 LSERDYF:** LSE ready interrupt flag

Set by hardware when the External Low Speed clock becomes stable and LSERDYDIE is set.

Cleared by software setting the LSERDYC bit.

0: No clock ready interrupt caused by the LSE oscillator

1: Clock ready interrupt caused by the LSE oscillator

**Bit 0 LSIRDYF:** LSI ready interrupt flag

Set by hardware when the internal low speed clock becomes stable and LSIRDYDIE is set.

Cleared by software setting the LSIRDYC bit.

0: No clock ready interrupt caused by the LSI oscillator

1: Clock ready interrupt caused by the LSI oscillator

**7.3.5 RCC AHB1 peripheral reset register (RCC\_AHB1RSTR)**

Address offset: 0x10

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |    |          |          |          |    |           |          |          |           |          |          |          |          |          |          |

Bits 31:30 Reserved, must be kept at reset value.

**Bit 29 OTGHSRST:** USB OTG HS module reset

Set and cleared by software.

0: does not reset the USB OTG HS module

1: resets the USB OTG HS module

Bits 28:26 Reserved, must be kept at reset value.

**Bit 25 ETHMACRST:** Ethernet MAC reset

Set and cleared by software.

0: does not reset Ethernet MAC

1: resets Ethernet MAC

Bits 24:23 Reserved, must be kept at reset value.

- Bit 22 **DMA2RST**: DMA2 reset  
Set and cleared by software.  
0: does not reset DMA2  
1: resets DMA2
- Bit 21 **DMA1RST**: DMA1 reset  
Set and cleared by software.  
0: does not reset DMA1  
1: resets DMA1
- Bits 20:13 Reserved, must be kept at reset value.
- Bit 12 **CRCRST**: CRC reset  
Set and cleared by software.  
0: does not reset CRC  
1: resets CRC
- Bits 11:9 Reserved, must be kept at reset value.
- Bit 8 **GPIORST**: IO port I reset  
Set and cleared by software.  
0: does not reset IO port I  
1: resets IO port I
- Bit 7 **GPIOHRST**: IO port H reset  
Set and cleared by software.  
0: does not reset IO port H  
1: resets IO port H
- Bits 6 **GPIOGRST**: IO port G reset  
Set and cleared by software.  
0: does not reset IO port G  
1: resets IO port G
- Bit 5 **GPIOFRST**: IO port F reset  
Set and cleared by software.  
0: does not reset IO port F  
1: resets IO port F
- Bit 4 **GPIOERST**: IO port E reset  
Set and cleared by software.  
0: does not reset IO port E  
1: resets IO port E
- Bit 3 **GPIODRST**: IO port D reset  
Set and cleared by software.  
0: does not reset IO port D  
1: resets IO port D

- Bit 2 **GPIOCRST**: IO port C reset  
Set and cleared by software.  
0: does not reset IO port C  
1: resets IO port C
- Bit 1 **GPIOBRST**: IO port B reset  
Set and cleared by software.  
0: does not reset IO port B  
1: resets IO port B
- Bit 0 **GPIOARST**: IO port A reset  
Set and cleared by software.  
0: does not reset IO port A  
1: resets IO port A

### 7.3.6 RCC AHB2 peripheral reset register (RCC\_AHB2RSTR)

Address offset: 0x14

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

|          |    |    |    |    |    |    |    |              |            |             |             |          |    |    |             |
|----------|----|----|----|----|----|----|----|--------------|------------|-------------|-------------|----------|----|----|-------------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22         | 21          | 20          | 19       | 18 | 17 | 16          |
| Reserved |    |    |    |    |    |    |    |              |            |             |             |          |    |    |             |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OTGFSRST**: USB OTG FS module reset

Set and cleared by software.

0: does not reset the USB OTG FS module

1: resets the USB OTG FS module

Bit 6 **RNGRST**: Random number generator module reset

Set and cleared by software.

0: does not reset the random number generator module

1: resets the random number generator module

Bit 5 **HASHRST**: Hash module reset

Set and cleared by software.

0: does not reset the HASH module

1: resets the HASH module

Bit 4 **CRYP RST**: Cryptographic module reset

Set and cleared by software.

0: does not reset the cryptographic module

1: resets the cryptographic module

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIRST**: Camera interface reset

Set and cleared by software.

0: does not reset the Camera interface

1: resets the Camera interface

### 7.3.7 RCC AHB3 peripheral reset register (RCC\_AHB3RSTR)

Address offset: 0x18

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |         |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|---------|----|

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |         | rw |

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **FSMCRST**: Flexible static memory controller module reset

Set and cleared by software.

0: does not reset the FSMC module

1: resets the FSMC module

### 7.3.8 RCC APB1 peripheral reset register (RCC\_APB1RSTR)

Address offset: 0x20

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |          |          |         |          |          |           |           |           |          |          |           |           |           |           |          |

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DACRST**: DAC reset

Set and cleared by software.

0: does not reset the DAC interface

1: resets the DAC interface

Bit 28 **PWRRST**: Power interface reset

Set and cleared by software.

0: does not reset the power interface

1: resets the power interface

Bit 27 Reserved, must be kept at reset value.

- Bit 26 **CAN2RST**: CAN2 reset  
Set and cleared by software.  
0: does not reset CAN2  
1: resets CAN2
- Bit 25 **CAN1RST**: CAN1 reset  
Set and cleared by software.  
0: does not reset CAN1  
1: resets CAN1
- Bit 24 Reserved, must be kept at reset value.
- Bit 23 **I2C3RST**: I2C3 reset  
Set and cleared by software.  
0: does not reset I2C3  
1: resets I2C3
- Bit 22 **I2C2RST**: I2C2 reset  
Set and cleared by software.  
0: does not reset I2C2  
1: resets I2C2
- Bit 21 **I2C1RST**: I2C1 reset  
Set and cleared by software.  
0: does not reset I2C1  
1: resets I2C1
- Bit 20 **UART5RST**: UART5 reset  
Set and cleared by software.  
0: does not reset UART5  
1: resets UART5
- Bit 19 **UART4RST**: USART4 reset  
Set and cleared by software.  
0: does not reset UART4  
1: resets UART4
- Bit 18 **USART3RST**: USART3 reset  
Set and cleared by software.  
0: does not reset USART3  
1: resets USART3
- Bit 17 **USART2RST**: USART2 reset  
Set and cleared by software.  
0: does not reset USART2  
1: resets USART2
- Bit 16 Reserved, must be kept at reset value.
- Bit 15 **SPI3RST**: SPI3 reset  
Set and cleared by software.  
0: does not reset SPI3  
1: resets SPI3
- Bit 14 **SPI2RST**: SPI2 reset  
Set and cleared by software.  
0: does not reset SPI2  
1: resets SPI2

Bits 13:12 Reserved, must be kept at reset value.

- Bit 11 **WWDGRST**: Window watchdog reset  
Set and cleared by software.  
0: does not reset the window watchdog  
1: resets the window watchdog

Bits 10:9 Reserved, must be kept at reset value.

- Bit 8 **TIM14RST**: TIM14 reset  
Set and cleared by software.  
0: does not reset TIM14  
1: resets TIM14

- Bit 7 **TIM13RST**: TIM13 reset  
Set and cleared by software.  
0: does not reset TIM13  
1: resets TIM13

- Bit 6 **TIM12RST**: TIM12 reset  
Set and cleared by software.  
0: does not reset TIM12  
1: resets TIM12

- Bit 5 **TIM7RST**: TIM7 reset  
Set and cleared by software.  
0: does not reset TIM7  
1: resets TIM7

- Bit 4 **TIM6RST**: TIM6 reset  
Set and cleared by software.  
0: does not reset TIM6  
1: resets TIM6

- Bit 3 **TIM5RST**: TIM5 reset  
Set and cleared by software.  
0: does not reset TIM5  
1: resets TIM5

- Bit 2 **TIM4RST**: TIM4 reset  
Set and cleared by software.  
0: does not reset TIM4  
1: resets TIM4

- Bit 1 **TIM3RST**: TIM3 reset  
Set and cleared by software.  
0: does not reset TIM3  
1: resets TIM3

- Bit 0 **TIM2RST**: TIM2 reset  
Set and cleared by software.  
0: does not reset TIM2  
1: resets TIM2

Bit 8 **ADCRST**: ADC interface reset (common to all ADCs)

Set and cleared by software.

0: does not reset the ADC interface

1: resets the ADC interface

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **USART6RST**: USART6 reset

Set and cleared by software.

0: does not reset USART6

1: resets USART6

Bit 4 **USART1RST**: USART1 reset

Set and cleared by software.

0: does not reset USART1

1: resets USART1

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8RST**: TIM8 reset

Set and cleared by software.

0: does not reset TIM8

1: resets TIM8

Bit 0 **TIM1RST**: TIM1 reset

Set and cleared by software.

0: does not reset TIM1

1: resets TIM1

**7.3.10 RCC AHB1 peripheral clock enable register (RCC\_AHB1ENR)**

Address offset: 0x30

Reset value: 0x0010 0000

Access: no wait state, word, half-word and byte access.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OTGHSULPIEN**: USB OTG HSULPI clock enable

Set and cleared by software. This bit must be cleared when the OTG\_HS is used in FS mode.

0: USB OTG HS ULPI clock disabled

1: USB OTG HS ULPI clock enabled

Bit 29 **OTGHSSEN**: USB OTG HS clock enable

Set and cleared by software.

0: USB OTG HS clock disabled

1: USB OTG HS clock enabled

Bit 28 **ETHMACPTPEN**: Ethernet PTP clock enable

Set and cleared by software.

0: Ethernet PTP clock disabled

1: Ethernet PTP clock enabled

Bit 27 **ETHMACRXEN**: Ethernet Reception clock enable

Set and cleared by software.

0: Ethernet Reception clock disabled

1: Ethernet Reception clock enabled

Bit 26 **ETHMACTXEN**: Ethernet Transmission clock enable

Set and cleared by software.

0: Ethernet Transmission clock disabled

1: Ethernet Transmission clock enabled

Bit 25 **ETHMACEN**: Ethernet MAC clock enable

Set and cleared by software.

0: Ethernet MAC clock disabled

1: Ethernet MAC clock enabled

Bits 24:23 Reserved, must be kept at reset value.

Bit 22 **DMA2EN**: DMA2 clock enable

Set and cleared by software.

0: DMA2 clock disabled

1: DMA2 clock enabled

- Bit 21 **DMA1EN**: DMA1 clock enable  
Set and cleared by software.  
0: DMA1 clock disabled  
1: DMA1 clock enabled
- Bit 20 **CCMDATARAMEN**: CCM data RAM clock enable  
Set and cleared by software.  
0: CCM data RAM clock disabled  
1: CCM data RAM clock enabled
- Bit 19 Reserved, must be kept at reset value.
- Bit 18 **BKPSRAMEN**: Backup SRAM interface clock enable  
Set and cleared by software.  
0: Backup SRAM interface clock disabled  
1: Backup SRAM interface clock enabled
- Bits 17:13 Reserved, must be kept at reset value.
- Bit 12 **CRCEN**: CRC clock enable  
Set and cleared by software.  
0: CRC clock disabled  
1: CRC clock enabled
- Bits 11:9 Reserved, must be kept at reset value.
- Bit 8 **GPIOEN**: IO port I clock enable  
Set and cleared by software.  
0: IO port I clock disabled  
1: IO port I clock enabled
- Bit 7 **GPIOHEN**: IO port H clock enable  
Set and cleared by software.  
0: IO port H clock disabled  
1: IO port H clock enabled
- Bit 6 **GPIOGEN**: IO port G clock enable  
Set and cleared by software.  
0: IO port G clock disabled  
1: IO port G clock enabled
- Bit 5 **GPIOFEN**: IO port F clock enable  
Set and cleared by software.  
0: IO port F clock disabled  
1: IO port F clock enabled
- Bit 4 **GPIOEEN**: IO port E clock enable  
Set and cleared by software.  
0: IO port E clock disabled  
1: IO port E clock enabled
- Bit 3 **GPIODEN**: IO port D clock enable  
Set and cleared by software.  
0: IO port D clock disabled  
1: IO port D clock enabled

Bit 2 **GPIOCEN**: IO port C clock enable

Set and cleared by software.

0: IO port C clock disabled

1: IO port C clock enabled

Bit 1 **GPIOBEN**: IO port B clock enable

Set and cleared by software.

0: IO port B clock disabled

1: IO port B clock enabled

Bit 0 **GPIOAEN**: IO port A clock enable

Set and cleared by software.

0: IO port A clock disabled

1: IO port A clock enabled

### 7.3.11 RCC AHB2 peripheral clock enable register (RCC\_AHB2ENR)

Address offset: 0x34

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |             |           |            |            |          |    |    |            |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OTGFSEN**: USB OTG FS clock enable

Set and cleared by software.

0: USB OTG FS clock disabled

1: USB OTG FS clock enabled

Bit 6 **RNGEN**: Random number generator clock enable

Set and cleared by software.

0: Random number generator clock disabled

1: Random number generator clock enabled

Bit 5 **HASHEN**: Hash modules clock enable

Set and cleared by software.

0: Hash modules clock disabled

1: Hash modules clock enabled

Bit 4 **CRYPEN**: Cryptographic modules clock enable

Set and cleared by software.

0: cryptographic module clock disabled

1: cryptographic module clock enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIEN**: Camera interface enable

Set and cleared by software.

0: Camera interface clock disabled

1: Camera interface clock enabled

### 7.3.12 RCC AHB3 peripheral clock enable register (RCC\_AHB3ENR)

Address offset: 0x38

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |        |    |

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DACEN**: DAC interface clock enable  
Set and cleared by software.  
0: DAC interface clock disabled  
1: DAC interface clock enable

Bit 28 **PWREN**: Power interface clock enable  
Set and cleared by software.  
0: Power interface clock disabled  
1: Power interface clock enable

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CAN2EN**: CAN 2 clock enable  
Set and cleared by software.  
0: CAN 2 clock disabled  
1: CAN 2 clock enabled

Bit 25 **CAN1EN**: CAN 1 clock enable  
Set and cleared by software.  
0: CAN 1 clock disabled  
1: CAN 1 clock enabled

Bit 24 Reserved, must be kept at reset value.

Bit 23 **I2C3EN**: I2C3 clock enable  
Set and cleared by software.  
0: I2C3 clock disabled  
1: I2C3 clock enabled

Bit 22 **I2C2EN**: I2C2 clock enable  
Set and cleared by software.  
0: I2C2 clock disabled  
1: I2C2 clock enabled

Bit 21 **I2C1EN**: I2C1 clock enable  
Set and cleared by software.  
0: I2C1 clock disabled  
1: I2C1 clock enabled

Bit 20 **UART5EN**: UART5 clock enable  
Set and cleared by software.  
0: UART5 clock disabled  
1: UART5 clock enabled

Bit 19 **UART4EN**: UART4 clock enable  
Set and cleared by software.  
0: UART4 clock disabled  
1: UART4 clock enabled

Bit 18 **USART3EN**: USART3 clock enable  
Set and cleared by software.  
0: USART3 clock disabled  
1: USART3 clock enabled

- Bit 17 **USART2EN**: USART2 clock enable  
Set and cleared by software.  
0: USART2 clock disabled  
1: USART2 clock enabled
- Bit 16 Reserved, must be kept at reset value.
- Bit 15 **SPI3EN**: SPI3 clock enable  
Set and cleared by software.  
0: SPI3 clock disabled  
1: SPI3 clock enabled
- Bit 14 **SPI2EN**: SPI2 clock enable  
Set and cleared by software.  
0: SPI2 clock disabled  
1: SPI2 clock enabled
- Bits 13:12 Reserved, must be kept at reset value.
- Bit 11 **WWDGEN**: Window watchdog clock enable  
Set and cleared by software.  
0: Window watchdog clock disabled  
1: Window watchdog clock enabled
- Bits 10:9 Reserved, must be kept at reset value.
- Bit 8 **TIM14EN**: TIM14 clock enable  
Set and cleared by software.  
0: TIM14 clock disabled  
1: TIM14 clock enabled
- Bit 7 **TIM13EN**: TIM13 clock enable  
Set and cleared by software.  
0: TIM13 clock disabled  
1: TIM13 clock enabled
- Bit 6 **TIM12EN**: TIM12 clock enable  
Set and cleared by software.  
0: TIM12 clock disabled  
1: TIM12 clock enabled
- Bit 5 **TIM7EN**: TIM7 clock enable  
Set and cleared by software.  
0: TIM7 clock disabled  
1: TIM7 clock enabled
- Bit 4 **TIM6EN**: TIM6 clock enable  
Set and cleared by software.  
0: TIM6 clock disabled  
1: TIM6 clock enabled
- Bit 3 **TIM5EN**: TIM5 clock enable  
Set and cleared by software.  
0: TIM5 clock disabled  
1: TIM5 clock enabled

Bit 0 **TIM2EN**: TIM2 clock enable  
Set and cleared by software.  
0: TIM2 clock disabled  
1: TIM2 clock enabled

- Bit 14 **SYSCFGEN**: System configuration controller clock enable  
Set and cleared by software.  
0: System configuration controller clock disabled  
1: System configuration controller clock enabled
- Bit 13 Reserved, must be kept at reset value.
- Bit 12 **SPI1EN**: SPI1 clock enable  
Set and cleared by software.  
0: SPI1 clock disabled  
1: SPI1 clock enabled
- Bit 11 **SDIOEN**: SDIO clock enable  
Set and cleared by software.  
0: SDIO module clock disabled  
1: SDIO module clock enabled
- Bit 10 **ADC3EN**: ADC3 clock enable  
Set and cleared by software.  
0: ADC3 clock disabled  
1: ADC3 clock disabled
- Bit 9 **ADC2EN**: ADC2 clock enable  
Set and cleared by software.  
0: ADC2 clock disabled  
1: ADC2 clock disabled
- Bit 8 **ADC1EN**: ADC1 clock enable  
Set and cleared by software.  
0: ADC1 clock disabled  
1: ADC1 clock disabled
- Bits 7:6 Reserved, must be kept at reset value.
- Bit 5 **USART6EN**: USART6 clock enable  
Set and cleared by software.  
0: USART6 clock disabled  
1: USART6 clock enabled
- Bit 4 **USART1EN**: USART1 clock enable  
Set and cleared by software.  
0: USART1 clock disabled  
1: USART1 clock enabled
- Bits 3:2 Reserved, must be kept at reset value.
- Bit 1 **TIM8EN**: TIM8 clock enable  
Set and cleared by software.  
0: TIM8 clock disabled  
1: TIM8 clock enabled
- Bit 0 **TIM1EN**: TIM1 clock enable  
Set and cleared by software.  
0: TIM1 clock disabled  
1: TIM1 clock enabled

### 7.3.15 RCC AHB1 peripheral clock enable in low power mode register (RCC\_AHB1LPENR)

Address offset: 0x50

Reset value: 0x7E67 91FF

Access: no wait state, word, half-word and byte access.

| 31            | 30                    | 29                | 28                 | 27            | 26            | 25                 | 24            | 23            | 22            | 21                | 20            | 19            | 18                  | 17                | 16                |

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OTGHSULPIPEN**: USB OTG HS ULPI clock enable during Sleep mode

Set and cleared by software. This bit must be cleared when the OTG\_HS is used in FS mode.

0: USB OTG HS ULPI clock disabled during Sleep mode

1: USB OTG HS ULPI clock enabled during Sleep mode

Bit 29 **OTGHSLPEN**: USB OTG HS clock enable during Sleep mode

Set and cleared by software.

0: USB OTG HS clock disabled during Sleep mode

1: USB OTG HS clock enabled during Sleep mode

Bit 28 **ETHMACPTLPEN**: Ethernet PTP clock enable during Sleep mode

Set and cleared by software.

0: Ethernet PTP clock disabled during Sleep mode

1: Ethernet PTP clock enabled during Sleep mode

Bit 27 **ETHMACRXLPEN**: Ethernet reception clock enable during Sleep mode

Set and cleared by software.

0: Ethernet reception clock disabled during Sleep mode

1: Ethernet reception clock enabled during Sleep mode

Bit 26 **ETHMACTXLPEN**: Ethernet transmission clock enable during Sleep mode

Set and cleared by software.

0: Ethernet transmission clock disabled during sleep mode

1: Ethernet transmission clock enabled during sleep mode

Bit 25 **ETHMACLPEN**: Ethernet MAC clock enable during Sleep mode

Set and cleared by software.

0: Ethernet MAC clock disabled during Sleep mode

1: Ethernet MAC clock enabled during Sleep mode

Bits 24:23 Reserved, must be kept at reset value.

- Bit 22 **DMA2LPEN**: DMA2 clock enable during Sleep mode  
Set and cleared by software.  
0: DMA2 clock disabled during Sleep mode  
1: DMA2 clock enabled during Sleep mode
- Bit 21 **DMA1LPEN**: DMA1 clock enable during Sleep mode  
Set and cleared by software.  
0: DMA1 clock disabled during Sleep mode  
1: DMA1 clock enabled during Sleep mode
- Bits 20:19 Reserved, must be kept at reset value.
- Bit 18 **BKPSRAMLPEN**: Backup SRAM interface clock enable during Sleep mode  
Set and cleared by software.  
0: Backup SRAM interface clock disabled during Sleep mode  
1: Backup SRAM interface clock enabled during Sleep mode
- Bit 17 **SRAM2LPEN**: SRAM 2 interface clock enable during Sleep mode  
Set and cleared by software.  
0: SRAM 2 interface clock disabled during Sleep mode  
1: SRAM 2 interface clock enabled during Sleep mode
- Bit 16 **SRAM1LPEN**: SRAM 1 interface clock enable during Sleep mode  
Set and cleared by software.  
0: SRAM 1 interface clock disabled during Sleep mode  
1: SRAM 1 interface clock enabled during Sleep mode
- Bit 15 **FLITFLPEN**: Flash interface clock enable during Sleep mode  
Set and cleared by software.  
0: Flash interface clock disabled during Sleep mode  
1: Flash interface clock enabled during Sleep mode
- Bits 14:13 Reserved, must be kept at reset value.
- Bit 12 **CRCLPEN**: CRC clock enable during Sleep mode  
Set and cleared by software.  
0: CRC clock disabled during Sleep mode  
1: CRC clock enabled during Sleep mode
- Bits 11:9 Reserved, must be kept at reset value.
- Bit 8 **GPIOLPEN**: IO port I clock enable during Sleep mode  
Set and cleared by software.  
0: IO port I clock disabled during Sleep mode  
1: IO port I clock enabled during Sleep mode
- Bit 7 **GPIOHPEN**: IO port H clock enable during Sleep mode  
Set and cleared by software.  
0: IO port H clock disabled during Sleep mode  
1: IO port H clock enabled during Sleep mode
- Bits 6 **GPIOGLPEN**: IO port G clock enable during Sleep mode  
Set and cleared by software.  
0: IO port G clock disabled during Sleep mode  
1: IO port G clock enabled during Sleep mode

Bit 5 **GPIOLFLEN**: IO port F clock enable during Sleep mode

Set and cleared by software.

0: IO port F clock disabled during Sleep mode

1: IO port F clock enabled during Sleep mode

Bit 4 **GPIOELPEN**: IO port E clock enable during Sleep mode

Set and cleared by software.

0: IO port E clock disabled during Sleep mode

1: IO port E clock enabled during Sleep mode

Bit 3 **GPIODLPEN**: IO port D clock enable during Sleep mode

Set and cleared by software.

0: IO port D clock disabled during Sleep mode

1: IO port D clock enabled during Sleep mode

Bit 2 **GPIOCLPEN**: IO port C clock enable during Sleep mode

Set and cleared by software.

0: IO port C clock disabled during Sleep mode

1: IO port C clock enabled during Sleep mode

Bit 1 **GPIOBLPEN**: IO port B clock enable during Sleep mode

Set and cleared by software.

0: IO port B clock disabled during Sleep mode

1: IO port B clock enabled during Sleep mode

Bit 0 **GPIOLPEN**: IO port A clock enable during sleep mode

Set and cleared by software.

0: IO port A clock disabled during Sleep mode

1: IO port A clock enabled during Sleep mode

### 7.3.16 RCC AHB2 peripheral clock enable in low power mode register (RCC\_AHB2LPENR)

Address offset: 0x54

Reset value: 0x0000 00F1

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |               |             |              |              |          |    |    |              |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OTGFSLPEN**: USB OTG FS clock enable during Sleep mode

Set and cleared by software.

0: USB OTG FS clock disabled during Sleep mode

1: USB OTG FS clock enabled during Sleep mode

Bit 6 **RNGLPEN**: Random number generator clock enable during Sleep mode

Set and cleared by software.

0: Random number generator clock disabled during Sleep mode

1: Random number generator clock enabled during Sleep mode

Bit 5 **HASHLPEN**: Hash modules clock enable during Sleep mode

Set and cleared by software.

0: Hash modules clock disabled during Sleep mode

1: Hash modules clock enabled during Sleep mode

Bit 4 **CRYPTLPEN**: Cryptography modules clock enable during Sleep mode

Set and cleared by software.

0: cryptography modules clock disabled during Sleep mode

1: cryptography modules clock enabled during Sleep mode

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMILPEN**: Camera interface enable during Sleep mode

Set and cleared by software.

0: Camera interface clock disabled during Sleep mode

1: Camera interface clock enabled during Sleep mode

### 7.3.17 RCC AHB3 peripheral clock enable in low power mode register (RCC\_AHB3LPENR)

Address offset: 0x58

Reset value: 0x0000 0001

Access: no wait state, word, half-word and byte access.

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |              |    |

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DACL PEN**: DAC interface clock enable during Sleep mode

Set and cleared by software.

0: DAC interface clock disabled during Sleep mode

1: DAC interface clock enabled during Sleep mode

Bit 28 **PWRLPEN**: Power interface clock enable during Sleep mode

Set and cleared by software.

0: Power interface clock disabled during Sleep mode

1: Power interface clock enabled during Sleep mode

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CAN2LPEN**: CAN 2 clock enable during Sleep mode

Set and cleared by software.

0: CAN 2 clock disabled during sleep mode

1: CAN 2 clock enabled during sleep mode

Bit 25 **CAN1LPEN**: CAN 1 clock enable during Sleep mode

Set and cleared by software.

0: CAN 1 clock disabled during Sleep mode

1: CAN 1 clock enabled during Sleep mode

Bit 24 Reserved, must be kept at reset value.

Bit 23 **I2C3LPEN**: I2C3 clock enable during Sleep mode

Set and cleared by software.

0: I2C3 clock disabled during Sleep mode

1: I2C3 clock enabled during Sleep mode

Bit 22 **I2C2LPEN**: I2C2 clock enable during Sleep mode

Set and cleared by software.

0: I2C2 clock disabled during Sleep mode

1: I2C2 clock enabled during Sleep mode

- Bit 21 **I2C1LPEN**: I2C1 clock enable during Sleep mode  
Set and cleared by software.  
0: I2C1 clock disabled during Sleep mode  
1: I2C1 clock enabled during Sleep mode
- Bit 20 **UART5LPEN**: UART5 clock enable during Sleep mode  
Set and cleared by software.  
0: UART5 clock disabled during Sleep mode  
1: UART5 clock enabled during Sleep mode
- Bit 19 **UART4LPEN**: UART4 clock enable during Sleep mode  
Set and cleared by software.  
0: UART4 clock disabled during Sleep mode  
1: UART4 clock enabled during Sleep mode
- Bit 18 **USART3LPEN**: USART3 clock enable during Sleep mode  
Set and cleared by software.  
0: USART3 clock disabled during Sleep mode  
1: USART3 clock enabled during Sleep mode
- Bit 17 **USART2LPEN**: USART2 clock enable during Sleep mode  
Set and cleared by software.  
0: USART2 clock disabled during Sleep mode  
1: USART2 clock enabled during Sleep mode
- Bit 16 Reserved, must be kept at reset value.
- Bit 15 **SPI3LPEN**: SPI3 clock enable during Sleep mode  
Set and cleared by software.  
0: SPI3 clock disabled during Sleep mode  
1: SPI3 clock enabled during Sleep mode
- Bit 14 **SPI2LPEN**: SPI2 clock enable during Sleep mode  
Set and cleared by software.  
0: SPI2 clock disabled during Sleep mode  
1: SPI2 clock enabled during Sleep mode
- Bits 13:12 Reserved, must be kept at reset value.
- Bit 11 **WWDGLPEN**: Window watchdog clock enable during Sleep mode  
Set and cleared by software.  
0: Window watchdog clock disabled during sleep mode  
1: Window watchdog clock enabled during sleep mode
- Bits 10:9 Reserved, must be kept at reset value.
- Bit 8 **TIM14LPEN**: TIM14 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM14 clock disabled during Sleep mode  
1: TIM14 clock enabled during Sleep mode
- Bit 7 **TIM13LPEN**: TIM13 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM13 clock disabled during Sleep mode  
1: TIM13 clock enabled during Sleep mode

- Bit 6 **TIM12LPEN**: TIM12 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM12 clock disabled during Sleep mode  
1: TIM12 clock enabled during Sleep mode
- Bit 5 **TIM7LPEN**: TIM7 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM7 clock disabled during Sleep mode  
1: TIM7 clock enabled during Sleep mode
- Bit 4 **TIM6LPEN**: TIM6 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM6 clock disabled during Sleep mode  
1: TIM6 clock enabled during Sleep mode
- Bit 3 **TIM5LPEN**: TIM5 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM5 clock disabled during Sleep mode  
1: TIM5 clock enabled during Sleep mode
- Bit 2 **TIM4LPEN**: TIM4 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM4 clock disabled during Sleep mode  
1: TIM4 clock enabled during Sleep mode
- Bit 1 **TIM3LPEN**: TIM3 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM3 clock disabled during Sleep mode  
1: TIM3 clock enabled during Sleep mode
- Bit 0 **TIM2LPEN**: TIM2 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM2 clock disabled during Sleep mode  
1: TIM2 clock enabled during Sleep mode

### 7.3.19 RCC APB2 peripheral clock enabled in low power mode register (RCC\_APB2LPENR)

Address offset: 0x64

Reset value: 0x0007 5F33

Access: no wait state, word, half-word and byte access.

|               |                    |               |              |              |              |              |              |          |                    |                    |          |              |               |               |              |

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **TIM11LPEN**: TIM11 clock enable during Sleep mode

Set and cleared by software.

0: TIM11 clock disabled during Sleep mode

1: TIM11 clock enabled during Sleep mode

Bit 17 **TIM10LPEN**: TIM10 clock enable during Sleep mode

Set and cleared by software.

0: TIM10 clock disabled during Sleep mode

1: TIM10 clock enabled during Sleep mode

Bit 16 **TIM9LPEN**: TIM9 clock enable during sleep mode

Set and cleared by software.

0: TIM9 clock disabled during Sleep mode

1: TIM9 clock enabled during Sleep mode

Bit 15 Reserved, must be kept at reset value.

Bit 14 **SYSCFGLPEN**: System configuration controller clock enable during Sleep mode

Set and cleared by software.

0: System configuration controller clock disabled during Sleep mode

1: System configuration controller clock enabled during Sleep mode

Bit 13 Reserved, must be kept at reset value.

Bit 12 **SPI1LPEN**: SPI1 clock enable during Sleep mode

Set and cleared by software.

0: SPI1 clock disabled during Sleep mode

1: SPI1 clock enabled during Sleep mode

Bit 11 **SDIOLPEN**: SDIO clock enable during Sleep mode

Set and cleared by software.

0: SDIO module clock disabled during Sleep mode

1: SDIO module clock enabled during Sleep mode

- Bit 10 **ADC3LPEN**: ADC 3 clock enable during Sleep mode  
Set and cleared by software.  
0: ADC 3 clock disabled during Sleep mode  
1: ADC 3 clock disabled during Sleep mode
- Bit 9 **ADC2LPEN**: ADC2 clock enable during Sleep mode  
Set and cleared by software.  
0: ADC2 clock disabled during Sleep mode  
1: ADC2 clock disabled during Sleep mode
- Bit 8 **ADC1LPEN**: ADC1 clock enable during Sleep mode  
Set and cleared by software.  
0: ADC1 clock disabled during Sleep mode  
1: ADC1 clock disabled during Sleep mode
- Bits 7:6 Reserved, must be kept at reset value.
- Bit 5 **USART6LPEN**: USART6 clock enable during Sleep mode  
Set and cleared by software.  
0: USART6 clock disabled during Sleep mode  
1: USART6 clock enabled during Sleep mode
- Bit 4 **USART1LPEN**: USART1 clock enable during Sleep mode  
Set and cleared by software.  
0: USART1 clock disabled during Sleep mode  
1: USART1 clock enabled during Sleep mode
- Bits 3:2 Reserved, must be kept at reset value.
- Bit 1 **TIM8LPEN**: TIM8 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM8 clock disabled during Sleep mode  
1: TIM8 clock enabled during Sleep mode
- Bit 0 **TIM1LPEN**: TIM1 clock enable during Sleep mode  
Set and cleared by software.  
0: TIM1 clock disabled during Sleep mode  
1: TIM1 clock enabled during Sleep mode

### 7.3.20 RCC Backup domain control register (RCC\_BDCR)

Address offset: 0x70

Reset value: 0x0000 0000, reset by Backup domain reset.

Access:  $0 \leq \text{wait state} \leq 3$ , word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

The LSEON, LSEBYP, RTCSEL and RTCEN bits in the [RCC Backup domain control register \(RCC\\_BDCR\)](#) are in the Backup domain. As a result, after Reset, these bits are write-protected and the DBP bit in the [PWR power control register \(PWR\\_CR\)](#) for [STM32F405xx/07xx and STM32F415xx/17xx](#) has to be set before these can be modified. Refer to [Section 7.1.1: System reset on page 213](#) for further information. These bits are only reset after a Backup domain Reset (see [Section 7.1.3: Backup domain reset](#)). Any internal or external Reset will not have any effect on these bits.

|          |          |    |    |    |    |             |    |          |    |    |    |    |        |        |       |

| 31       | 30       | 29 | 28 | 27 | 26 | 25          | 24 | 23       | 22 | 21 | 20 | 19 | 18     | 17     | 16    |
| Reserved |          |    |    |    |    |             |    |          |    |    |    |    |        |        | BDRST |
|          |          |    |    |    |    |             |    |          |    |    |    |    |        |        | rw    |
| 15       | 14       | 13 | 12 | 11 | 10 | 9           | 8  | 7        | 6  | 5  | 4  | 3  | 2      | 1      | 0     |
| RTCEN    | Reserved |    |    |    |    | RTCSEL[1:0] |    | Reserved |    |    |    |    | LSEBYP | LSERDY | LSEON |
| rw       |          |    |    |    |    | rw          | rw |          |    |    |    |    | rw     | r      | rw    |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset

Set and cleared by software.

0: Reset not activated

1: Resets the entire Backup domain

*Note: The BKPSRAM is not affected by this reset, the only way of resetting the BKPSRAM is through the Flash interface when a protection level change from level 1 to level 0 is requested.*

Bit 15 **RTCEN**: RTC clock enable

Set and cleared by software.

0: RTC clock disabled

1: RTC clock enabled

Bits 14:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**: RTC clock source selection

Set by software to select the clock source for the RTC. Once the RTC clock source has been selected, it cannot be changed anymore unless the Backup domain is reset. The BDRST bit can be used to reset them.

00: No clock

01: LSE oscillator clock used as the RTC clock

10: LSI oscillator clock used as the RTC clock

11: HSE oscillator clock divided by a programmable prescaler (selection through the RTCPRE[4:0] bits in the RCC clock configuration register (RCC\_CFGR)) used as the RTC clock

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **LSEBYP**: External low-speed oscillator bypass

Set and cleared by software to bypass the oscillator. This bit can be written only when the LSE clock is disabled.

0: LSE oscillator not bypassed  
1: LSE oscillator bypassed

Bit 1 **LSERDY**: External low-speed oscillator ready

Set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after 6 external low-speed oscillator clock cycles.

0: LSE clock not ready  
1: LSE clock ready

Bit 0 **LSEON**: External low-speed oscillator enable

Set and cleared by software.

0: LSE clock OFF  
1: LSE clock ON

### 7.3.21 RCC clock control & status register (RCC\_CSR)

Address offset: 0x74

Reset value: 0x0E00 0000, reset by system reset, except reset flags by power reset only.

Access:  $0 \leq \text{wait state} \leq 3$ , word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

|              |              |              |             |             |             |             |      |          |    |    |    |    |        |       |    |
|--------------|--------------|--------------|-------------|-------------|-------------|-------------|------|----------|----|----|----|----|--------|-------|----|

| Reserved     |              |              |             |             |             |             |      |          |    |    |    |    | LSIRDY | LSION |    |
|              |              |              |             |             |             |             |      |          |    |    |    |    | r      | rw    |    |

Bit 31 **LPWRRSTF**: Low-power reset flag

Set by hardware when a Low-power management reset occurs.  
Cleared by writing to the RMVF bit.

0: No Low-power management reset occurred  
1: Low-power management reset occurred

For further information on Low-power management reset, refer to [Low-power management reset](#).

Bit 30 **WWDGRSTF**: Window watchdog reset flag

Set by hardware when a window watchdog reset occurs.  
Cleared by writing to the RMVF bit.

0: No window watchdog reset occurred  
1: Window watchdog reset occurred

Bit 29 **IWDGRSTF**: Independent watchdog reset flag

Set by hardware when an independent watchdog reset from V<sub>DD</sub> domain occurs.  
Cleared by writing to the RMVF bit.

0: No watchdog reset occurred  
1: Watchdog reset occurred

- Bit 28 **SFTRSTF**: Software reset flag  
Set by hardware when a software reset occurs.  
Cleared by writing to the RMVF bit.  
0: No software reset occurred  
1: Software reset occurred
- Bit 27 **PORRSTF**: POR/PDR reset flag  
Set by hardware when a POR/PDR reset occurs.  
Cleared by writing to the RMVF bit.  
0: No POR/PDR reset occurred  
1: POR/PDR reset occurred
- Bit 26 **PINRSTF**: PIN reset flag  
Set by hardware when a reset from the NRST pin occurs.  
Cleared by writing to the RMVF bit.  
0: No reset from NRST pin occurred  
1: Reset from NRST pin occurred
- Bit 25 **BORRSTF**: BOR reset flag  
Cleared by software by writing the RMVF bit.  
Set by hardware when a POR/PDR or BOR reset occurs.  
0: No POR/PDR or BOR reset occurred  
1: POR/PDR or BOR reset occurred
- Bit 24 **RMVF**: Remove reset flag  
Set by software to clear the reset flags.  
0: No effect  
1: Clear the reset flags
- Bits 23:2 Reserved, must be kept at reset value.
- Bit 1 **LSIRDY**: Internal low-speed oscillator ready  
Set and cleared by hardware to indicate when the internal RC 40 kHz oscillator is stable.  
After the LSION bit is cleared, LSIRDY goes low after 3 LSI clock cycles.  
0: LSI RC oscillator not ready  
1: LSI RC oscillator ready
- Bit 0 **LSION**: Internal low-speed oscillator enable  
Set and cleared by software.  
0: LSI RC oscillator OFF  
1: LSI RC oscillator ON

### 7.3.22 RCC spread spectrum clock generation register (RCC\_SSCGR)

Address offset: 0x80

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access.

The spread spectrum clock generation is available only for the main PLL.

The RCC\_SSCGR register must be written either before the main PLL is enabled or after the main PLL disabled.

**Note:** For full details about PLL spread spectrum clock generation (SSCG) characteristics, refer to the “Electrical characteristics” section in your device datasheet.

|            |                   |          |    |         |    |    |    |    |    |    |    |    |    |    |    |

Bit 31 **SSCGEN**: Spread spectrum modulation enable

Set and cleared by software.

0: Spread spectrum modulation DISABLE. (To write after clearing CR[24]=PLLON bit)

1: Spread spectrum modulation ENABLE. (To write before setting CR[24]=PLLON bit)

Bit 30 **SPREADSEL**: Spread Select

Set and cleared by software.

To write before to set CR[24]=PLLON bit.

0: Center spread

1: Down spread

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:13 **INCSTEP**: Incrementation step

Set and cleared by software. To write before setting CR[24]=PLLON bit.

Configuration input for modulation profile amplitude.

Bits 12:0 **MODPER**: Modulation period

Set and cleared by software. To write before setting CR[24]=PLLON bit.

Configuration input for modulation profile period.

### 7.3.23 RCC PLLI2S configuration register (RCC\_PLLI2SCFGR)

Address offset: 0x84

Reset value: 0x2000 3000

Access: no wait state, word, half-word and byte access.

This register is used to configure the PLLI2S clock outputs according to the formulas:

- $f_{(VCO \text{ clock})} = f_{(PLLI2S \text{ clock input})} \times (PLLI2SN / PLLM)$
- $f_{(PLL \text{ I2S clock output})} = f_{(VCO \text{ clock})} / PLLI2SR$

|          |           |           |           |           |           |           |           |           |           |          |    |    |    |    |    |
|----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|----------|----|----|----|----|----|
| 31       | 30        | 29        | 28        | 27        | 26        | 25        | 24        | 23        | 22        | 21       | 20 | 19 | 18 | 17 | 16 |
| Reserved | PLLI2S R2 | PLLI2S R1 | PLLI2S R0 | Reserved  |           |           |           |           |           |          |    |    |    |    |    |
|          | rw        | rw        | rw        |           |           |           |           |           |           |          |    |    |    |    |    |
| 15       | 14        | 13        | 12        | 11        | 10        | 9         | 8         | 7         | 6         | 5        | 4  | 3  | 2  | 1  | 0  |
| Reserved | PLLI2SN 8 | PLLI2SN 7 | PLLI2SN 6 | PLLI2SN 5 | PLLI2SN 4 | PLLI2SN 3 | PLLI2SN 2 | PLLI2SN 1 | PLLI2SN 0 | Reserved |    |    |    |    |    |
|          | rw        | rw        | rw        | rw        | rw        | rw        | rw        | rw        | rw        |          |    |    |    |    |    |

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **PLLI2SR**: PLLI2S division factor for I2S clocks

Set and cleared by software to control the I2S clock frequency. These bits should be written only if the PLLI2S is disabled. The factor must be chosen in accordance with the prescaler values inside the I2S peripherals, to reach 0.3% error when using standard crystals and 0% error with audio crystals. For more information about I2S clock frequency and precision, refer to [Section 28.4.4: Clock generator](#) in the I2S chapter.

**Caution:** The I2Ss requires a frequency lower than or equal to 192 MHz to work correctly.

I2S clock frequency = VCO frequency / PLLR with  $2 \leq PLLR \leq 7$

000: PLLR = 0, wrong configuration

001: PLLR = 1, wrong configuration

010: PLLR = 2

...

111: PLLR = 7

Bits 27:15 Reserved, must be kept at reset value.

Bits 14:6 **PLLI2SN**: PLLI2S multiplication factor for VCO

These bits are set and cleared by software to control the multiplication factor of the VCO.  
These bits can be written only when PLLI2S is disabled. Only half-word and word accesses are allowed to write these bits.

**Caution:** The software has to set these bits correctly to ensure that the VCO output frequency is between 100 and 432 MHz.

VCO output frequency = VCO input frequency × PLLI2SN with  $50 \leq \text{PLLI2SN} \leq 432$

000000000: PLLI2SN = 0, wrong configuration

000000001: PLLI2SN = 1, wrong configuration

...

000110010: PLLI2SN = 50

...

001100011: PLLI2SN = 99

001100100: PLLI2SN = 100

001100101: PLLI2SN = 101

001100110: PLLI2SN = 102

...

110110000: PLLI2SN = 432

110110001: PLLI2SN = 433, wrong configuration

...

111111111: PLLI2SN = 511, wrong configuration

*Note: Multiplication factors ranging from 50 and 99 are possible for VCO input frequency higher than 1 MHz. However care must be taken that the minimum VCO output frequency respects the value specified above.*

Bits 5:0 Reserved, must be kept at reset value.

### 7.3.24 RCC register map

Table 34 gives the register map and reset values.

Table 34. RCC register map and reset values

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 8 General-purpose I/Os (GPIO)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 8.1 GPIO introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR and GPIOx\_PUPDR), two 32-bit data registers (GPIOx\_IDR and GPIOx\_ODR), a 32-bit set/reset register (GPIOx\_BSRR), a 32-bit locking register (GPIOx\_LCKR) and two 32-bit alternate function selection register (GPIOx\_AFRH and GPIOx\_AFLR).

### 8.2 GPIO main features

- Up to 16 I/Os under control
- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx\_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx\_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx\_BSRR) for bitwise write access to GPIOx\_ODR
- Locking mechanism (GPIOx\_LCKR) provided to freeze the I/O configuration
- Analog function
- Alternate function input/output selection registers (at most 16 AFs per I/O)
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

### 8.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx\_BSRR register is to allow atomic read/modify accesses to any of the GPIO registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

Figure 25 shows the basic structure of a 5 V tolerant I/O port bit. Table 39 gives the possible port bit configurations.

**Figure 25. Basic structure of a five-volt tolerant I/O port bit**

1.  $V_{DD\_FT}$  is a potential specific to five-volt tolerant I/Os and different from  $V_{DD}$ .

|                   | x         | x                   | x | 1                 | 0 |                           |          |
|                   | x         | x                   | x | 1                 | 1 |                           |          |

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

### 8.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and the I/O ports are configured in input floating mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDAT in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO in floating state

When the pin is configured as output, the value written to the output data register (GPIOx\_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the N-MOS is activated when 0 is output).

The input data register (GPIOx\_IDR) captures the data present on the I/O pin at every AHB1 clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx\_PUPDR register.

### 8.3.2 I/O pin multiplexer and mapping

The microcontroller I/O pins are connected to onboard peripherals/modules through a multiplexer that allows only one peripheral's alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals sharing the same I/O pin.

Each I/O pin has a multiplexer with sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx\_AFRL (for pin 0 to 7) and GPIOx\_AFRH (for pin 8 to 15) registers:

- After reset all I/Os are connected to the system's alternate function 0 (AF0)
- The peripherals' alternate functions are mapped from AF1 to AF13
- Cortex<sup>®</sup>-M4 with FPU EVENTOUT is mapped on AF15

This structure is shown in [Figure 26](#) below.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, proceed as follows:

- **System function**

Connect the I/O to AF0 and configure it depending on the function used:

- JTAG/SWD, after each device reset these pins are assigned as dedicated pins immediately usable by the debugger host (not controlled by the GPIO controller)
- RTC\_REFIN: this pin should be configured in Input floating mode
- MCO1 and MCO2: these pins have to be configured in alternate function mode.

*Note:* The user can disable some or all of the JTAG/SWD pins and so release the associated pins for GPIO usage (released pins highlighted in gray in the table).

For more details refer to [Section 7.2.10: Clock-out capability](#) and [Section 6.2.10: Clock-out capability](#).

Table 36. Flexible SWJ-DP pin assignment

| Available debug ports                         | SWJ I/O pin assigned |                     |             |            |              |
|-----------------------------------------------|----------------------|---------------------|-------------|------------|--------------|
|                                               | PA13 / JTMS / SWDIO  | PA14 / JTCK / SWCLK | PA15 / JTDI | PB3 / JTDO | PB4 / NJTRST |
| Full SWJ (JTAG-DP + SW-DP) - Reset state      | X                    | X                   | X           | X          | X            |
| Full SWJ (JTAG-DP + SW-DP) but without NJTRST | X                    | X                   | X           | X          |              |
| JTAG-DP Disabled and SW-DP Enabled            | X                    | X                   |             |            |              |
| JTAG-DP Disabled and SW-DP Disabled           | Released             |                     |             |            |              |

- **GPIO**

Configure the desired I/O as output or input in the GPIOx\_MODER register.

- **Peripheral alternate function**

For the ADC and DAC, configure the desired I/O as analog in the GPIOx\_MODER register.

For other peripherals:

- Configure the desired I/O as an alternate function in the GPIOx\_MODER register
- Select the type, pull-up/pull-down and output speed via the GPIOx\_OTYPER, GPIOx\_PUPDR and GPIOx\_OSPEEDR registers, respectively
- Connect the I/O to the desired AFx in the GPIOx\_AFR1 or GPIOx\_AFR2 register

- **EVENTOUT**

Configure the I/O pin used to output the Cortex®-M4 with FPU EVENTOUT signal by connecting it to AF15

*Note:* **EVENTOUT** is not mapped onto the following I/O pins: PC13, PC14, PC15, PH0, PH1 and PI8.

Refer to the “Alternate function mapping” table in the datasheets for the detailed mapping of the system and peripherals’ alternate function I/O pins.

**Figure 26. Selecting an alternate function on STM32F405xx/07xx and STM32F415xx/17xx**

1. Configured in FS.

**Figure 27. Selecting an alternate function on STM32F42xxx and STM32F43xxx**

For pins 0 to 7, the GPIOx\_AFRL[31:0] register selects the dedicated alternate function

For pins 8 to 15, the GPIOx\_AFRH[31:0] register selects the dedicated alternate function

MS60208V1

1. Configured in FS.

### 8.3.3 I/O port control registers

Each of the GPIOs has four 32-bit memory-mapped control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR) to configure up to 16 I/Os.

The GPIOx\_MODER register is used to select the I/O direction (input, output, AF, analog). The GPIOx\_OTYPER and GPIOx\_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed (the I/O speed pins are directly connected to the corresponding GPIOx\_OSPEEDR register bits whatever the I/O direction). The GPIOx\_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

### 8.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx\_IDR and GPIOx\_ODR). GPIOx\_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx\_IDR), a read-only register.

See [Section 8.4.5: GPIO port input data register \(GPIOx\\_IDR\) \(x = A..I/J/K\)](#) and [Section 8.4.6: GPIO port output data register \(GPIOx\\_ODR\) \(x = A..I/J/K\)](#) for the register descriptions.

### 8.3.5 I/O data bitwise handling

The bit set reset register (GPIOx\_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx\_ODR). The bit set reset register has twice the size of GPIOx\_ODR.

To each bit in GPIOx\_ODR, correspond two control bits in GPIOx\_BSRR: BSRR(i) and BSRR(i+SIZE). When written to 1, bit BSRR(i) sets the corresponding ODR(i) bit. When written to 1, bit BSRR(i+SIZE) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx\_BSRR does not have any effect on the corresponding bit in GPIOx\_ODR. If there is an attempt to both set and reset a bit in GPIOx\_BSRR, the set action takes priority.

Using the GPIOx\_BSRR register to change the values of individual bits in GPIOx\_ODR is a “one-shot” effect that does not lock the GPIOx\_ODR bits. The GPIOx\_ODR bits can always be accessed directly. The GPIOx\_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx\_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB1 write access.

### 8.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx\_LCKR register. The frozen registers are GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH.

To write the GPIOx\_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU or peripheral reset. Each GPIOx\_LCKR bit

freezes the corresponding bit in the control registers (GPIOx\_MODER, GPIOx\_OTYPER, GPIOx\_OSPEEDR, GPIOx\_PUPDR, GPIOx\_AFRL and GPIOx\_AFRH).

The LOCK sequence (refer to [Section 8.4.8: GPIO port configuration lock register \(GPIOx\\_LCKR\) \(x = A..I/J/K\)](#)) can only be performed using a word (32-bit long) access to the GPIOx\_LCKR register due to the fact that GPIOx\_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in [Section 8.4.8: GPIO port configuration lock register \(GPIOx\\_LCKR\) \(x = A..I/J/K\)](#).

### 8.3.7 I/O alternate function input/output

Two registers are provided to select one out of the sixteen alternate function inputs/outputs available for each I/O. With these registers, you can connect an alternate function to some other pin as required by your application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx\_AFRL and GPIOx\_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of one I/O.

To know which functions are multiplexed on each GPIO pin, refer to the datasheets.

*Note:* The application is allowed to select one of the possible peripheral functions for each I/O at a time.

### 8.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode, refer to [Section 12.2: External interrupt/event controller \(EXTI\)](#) and [Section 12.2.3: Wakeup event management](#).

### 8.3.9 Input configuration

When the I/O port is programmed as Input:

- the output buffer is disabled
- the Schmitt trigger input is activated
- the pull-up and pull-down resistors are activated depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB1 clock cycle
- A read access to the input data register provides the I/O State

[Figure 28](#) shows the input configuration of the I/O port bit.

Figure 28. Input floating/pull up/pull down configurations

### 8.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB1 clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value

*Figure 29* shows the output configuration of the I/O port bit.

Figure 29. Output configuration

### 8.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured as open-drain or push-pull
- The output buffer is driven by the signal coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx\_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB1 clock cycle
- A read access to the input data register gets the I/O state

Figure 30 shows the Alternate function configuration of the I/O port bit.

Figure 30. Alternate function configuration

### 8.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled
- Read access to the input data register gets the value “0”

**Note:** *In the analog configuration, the I/O pins cannot be 5 Volt tolerant.*

*Figure 31* shows the high-impedance, analog-input configuration of the I/O port bit.

**Figure 31. High impedance-analog configuration**

### 8.3.13 Using the OSC32\_IN/OSC32\_OUT pins as GPIO PC14/PC15 port pins

The LSE oscillator pins OSC32\_IN and OSC32\_OUT can be used as general-purpose PC14 and PC15 I/Os, respectively, when the LSE oscillator is off. The PC14 and PC15 I/Os are only configured as LSE oscillator pins OSC32\_IN and OSC32\_OUT when the LSE oscillator is ON. This is done by setting the LSEON bit in the RCC\_BDCR register. The LSE has priority over the GPIO function.

**Note:** *The PC14/PC15 GPIO functionality is lost when the 1.2 V domain is powered off (by the device entering the standby mode) or when the backup domain is supplied by V<sub>BAT</sub> (V<sub>DD</sub> no more supplied). In this case the I/Os are set in analog input mode.*

### 8.3.14 Using the OSC\_IN/OSC\_OUT pins as GPIO PH0/PH1 port pins

The HSE oscillator pins OSC\_IN/OSC\_OUT can be used as general-purpose PH0/PH1 I/Os, respectively, when the HSE oscillator is OFF. (after reset, the HSE oscillator is off). The PH0/PH1 I/Os are only configured as OSC\_IN/OSC\_OUT HSE oscillator pins when the HSE oscillator is ON. This is done by setting the HSEON bit in the RCC\_CR register. The HSE has priority over the GPIO function.

### 8.3.15 Selection of RTC\_AF1 and RTC\_AF2 alternate functions

The STM32F4xx feature two GPIO pins RTC\_AF1 and RTC\_AF2 that can be used for the detection of a tamper or time stamp event, or RTC\_ALARM, or RTC\_CALIB RTC outputs.

- The RTC\_AF1 (PC13) can be used for the following purposes:

RTC\_ALARM output: this output can be RTC Alarm A, RTC Alarm B or RTC Wakeup depending on the OSEL[1:0] bits in the RTC\_CR register

- RTC\_CALIB output: this feature is enabled by setting the COE[23] in the RTC\_CR register
- RTC\_TAMP1: tamper event detection
- RTC\_TS: time stamp event detection

The RTC\_AF2 (PI8) can be used for the following purposes:

- RTC\_TAMP1: tamper event detection
- RTC\_TAMP2: tamper event detection
- RTC\_TS: time stamp event detection

The selection of the corresponding pin is performed through the RTC\_TAFCR register as follows:

- TAMP1INSEL is used to select which pin is used as the RTC\_TAMP1 tamper input
- TSINSEL is used to select which pin is used as the RTC\_TS time stamp input
- ALARMOUTTYPE is used to select whether the RTC\_ALARM is output in push-pull or open-drain mode

The output mechanism follows the priority order listed in [Table 37](#) and [Table 38](#).

**Table 37. RTC\_AF1 pin<sup>(1)</sup>**

| Pin configuration and function       | RTC_ALARM enabled | RTC_CALIB enabled | Tamper enabled | Time stamp enabled | TAMP1INSEL TAMPER1 pin selection | TSINSEL TIMESTAMP pin selection | ALARMOUTTYPE RTC_ALARM configuration |
|--------------------------------------|-------------------|-------------------|----------------|--------------------|----------------------------------|---------------------------------|--------------------------------------|
| Alarm out output OD                  | 1                 | Don't care        | Don't care     | Don't care         | Don't care                       | Don't care                      | 0                                    |

## 8.4 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to [Table 39](#).

The GPIO registers can be accessed by byte (8 bits), half-words (16 bits) or words (32 bits).

### 8.4.1 GPIO port mode register (GPIOx\_MODER) (x = A..I/J/K)

Address offset: 0x00

Reset values:

- 0xA800 0000 for port A
- 0x0000 0280 for port B
- 0x0000 0000 for other ports

|              |    |              |    |              |    |              |    |              |    |              |    |             |    |             |    |
|--------------|----|--------------|----|--------------|----|--------------|----|--------------|----|--------------|----|-------------|----|-------------|----|

Bits 2y:2y+1 **MODERy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O direction mode.

00: Input (reset state)

01: General purpose output mode

10: Alternate function mode

11: Analog mode

### 8.4.2 GPIO port output type register (GPIOx\_OTYPER) (x = A..I/J/K)

Address offset: 0x04

Reset value: 0x0000 0000

|          |      |      |      |      |      |     |     |     |     |     |     |     |     |     |     |
|----------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31       | 30   | 29   | 28   | 27   | 26   | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| Reserved |      |      |      |      |      |     |     |     |     |     |     |     |     |     |     |

| rW       | rW   | rW   | rW   | rW   | rW   | rW  | rW  | rW  | rW  | rW  | rW  | rW  | rW  | rW  | rW  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the output type of the I/O port.

0: Output push-pull (reset state)

1: Output open-drain

### 8.4.3 GPIO port output speed register (GPIOx\_OSPEEDR) (x = A..I/J/K)

Address offset: 0x08

Reset values:

- 0x0C00 0000 for port A
- 0x0000 00C0 for port B
- 0x0000 0000 for other ports

|                 |    |                 |    |                 |    |                 |    |                 |    |                 |    |                |    |                |    |
|-----------------|----|-----------------|----|-----------------|----|-----------------|----|-----------------|----|-----------------|----|----------------|----|----------------|----|
| 31              | 30 | 29              | 28 | 27              | 26 | 25              | 24 | 23              | 22 | 21              | 20 | 19             | 18 | 17             | 16 |

Bits 2y:2y+1 **OSPEEDRy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very high speed

*Note: Refer to the product datasheets for the values of OSPEEDRy bits versus V<sub>DD</sub> range and external load.*

### 8.4.4 GPIO port pull-up/pull-down register (GPIOx\_PUPDR) (x = A..I/J/K)

Address offset: 0x0C

Reset values:

- 0x6400 0000 for port A
- 0x0000 0100 for port B
- 0x0000 0000 for other ports

|               |    |               |    |               |    |               |    |               |    |               |    |              |    |              |    |

Bits 2y:2y+1 **PUPDRy[1:0]**: Port x configuration bits (y = 0..15)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

#### 8.4.5 GPIO port input data register (GPIOx\_IDR) (x = A..I/J/K)

Address offset: 0x10

Reset value: 0x0000 XXXX (where X means undefined)

|          |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|----------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| 31       | 30    | 29    | 28    | 27    | 26    | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Reserved |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
| 15       | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| IDR15    | IDR14 | IDR13 | IDR12 | IDR11 | IDR10 | IDR9 | IDR8 | IDR7 | IDR6 | IDR5 | IDR4 | IDR3 | IDR2 | IDR1 | IDR0 |
| r        | r     | r     | r     | r     | r     | r    | r    | r    | r    | r    | r    | r    | r    | r    | r    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDRy**: Port input data (y = 0..15)

These bits are read-only and can be accessed in word mode only. They contain the value of the corresponding I/O port. 

#### 8.4.6 GPIO port output data register (GPIOx\_ODR) (x = A..I/J/K)

Address offset: 0x14

Reset value: 0x0000 0000

|          |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|----------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| 31       | 30    | 29    | 28    | 27    | 26    | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Reserved |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
| 15       | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| ODR15    | ODR14 | ODR13 | ODR12 | ODR11 | ODR10 | ODR9 | ODR8 | ODR7 | ODR6 | ODR5 | ODR4 | ODR3 | ODR2 | ODR1 | ODR0 |
| r/w      | r/w   | r/w   | r/w   | r/w   | r/w   | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODRy**: Port output data (y = 0..15)

These bits can be read and written by software.

*Note: For atomic bit set/reset, the ODR bits can be individually set and reset by writing to the GPIOx\_BSRR register (x = A..I/J/K).*

### 8.4.7 GPIO port bit set/reset register (GPIOx\_BSRR) (x = A..I/J/K)

Address offset: 0x18

Reset value: 0x0000 0000

|      |      |      |      |      |      |     |     |     |     |     |     |     |     |     |     |
|------|------|------|------|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31   | 30   | 29   | 28   | 27   | 26   | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| BR15 | BR14 | BR13 | BR12 | BR11 | BR10 | BR9 | BR8 | BR7 | BR6 | BR5 | BR4 | BR3 | BR2 | BR1 | BR0 |
| w    | w    | w    | w    | w    | w    | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   |
| 15   | 14   | 13   | 12   | 11   | 10   | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| BS15 | BS14 | BS13 | BS12 | BS11 | BS10 | BS9 | BS8 | BS7 | BS6 | BS5 | BS4 | BS3 | BS2 | BS1 | BS0 |
| w    | w    | w    | w    | w    | w    | w   | w   | w   | w   | w   | w   | w   | w   | w   | w   |

Bits 31:16 **BRy**: Port x reset bit y (y = 0..15)

These bits are write-only and can be accessed in word, half-word or byte mode. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODRx bit

1: Resets the corresponding ODRx bit

*Note: If both BSx and BRx are set, BSx has priority.*

Bits 15:0 **BSy**: Port x set bit y (y = 0..15)

These bits are write-only and can be accessed in word, half-word or byte mode. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODRx bit

1: Sets the corresponding ODRx bit

### 8.4.8 GPIO port configuration lock register (GPIOx\_LCKR) (x = A..I/J/K)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU or peripheral reset.

*Note: A specific write sequence is used to write to the GPIOx\_LCKR register. Only word access (32-bit long) is allowed during this write sequence.*

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

Access: 32-bit word only, read/write register

|          |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|----------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| 31       | 30    | 29    | 28    | 27    | 26    | 25   | 24   | 23   | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Reserved |       |       |       |       |       |      |      |      |      |      |      |      |      |      | LCKK |
|          |       |       |       |       |       |      |      |      |      |      |      |      |      |      | r/w  |
| 15       | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| LCK15    | LCK14 | LCK13 | LCK12 | LCK11 | LCK10 | LCK9 | LCK8 | LCK7 | LCK6 | LCK5 | LCK4 | LCK3 | LCK2 | LCK1 | LCK0 |
| r/w      | r/w   | r/w   | r/w   | r/w   | r/w   | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK[16]**: Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx\_LCKR register is locked until an MCU reset or a peripheral reset occurs.

LOCK key write sequence:

WR LCKR[16] = '1' + LCKR[15:0]

WR LCKR[16] = '0' + LCKR[15:0]

WR LCKR[16] = '1' + LCKR[15:0]

RD LCKR

RD LCKR[16] = '1' (this read operation is optional but it confirms that the lock is active)

*Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.*

*Any error in the lock sequence aborts the lock.*

*After the first lock sequence on any bit of the port, any read access on the LCKK bit returns '1' until the next CPU reset.*

Bits 15:0 **LCKy**: Port x lock bit y (y = 0..15)

These bits are read/write but can only be written when the LCKK bit is '0'.

0: Port configuration not locked

1: Port configuration locked

## 8.4.9 GPIO alternate function low register (GPIOx\_AFRL) (x = A..I/J/K)

Address offset: 0x20

Reset value: 0x0000 0000

|            |    |    |    |            |    |    |    |            |    |    |    |            |    |    |    |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 9 System configuration controller (SYSCFG)

The system configuration controller is mainly used to remap the memory accessible in the code area, select the Ethernet PHY interface and manage the external interrupt line connection to the GPIOs.

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 9.1 I/O compensation cell

By default the I/O compensation cell is not used. However when the I/O output buffer speed is configured in 50 MHz or 100 MHz mode, it is recommended to use the compensation cell for slew rate control on I/O  $t_{r(I/O)out}/t_{r(I/O)out}$  commutation to reduce the I/O noise on power supply.

When the compensation cell is enabled, a READY flag is set to indicate that the compensation cell is ready and can be used. The I/O compensation cell can be used only when the supply voltage ranges from 2.4 to 3.6 V.

### 9.2 SYSCFG registers for STM32F405xx/07xx and STM32F415xx/17xx

#### 9.2.1 SYSCFG memory remap register (SYSCFG\_MEMRMP)

This register is used for specific configurations on memory remap:

- Two bits are used to configure the type of memory accessible at address 0x0000 0000. These bits are used to select the physical remap by software and so, bypass the BOOT pins.
- After reset these bits take the value selected by the BOOT pins. When booting from main Flash memory with BOOT pins set to 10 [(BOOT1,BOOT0) = (1,0)] this register takes the value 0x00.

When the FSMC is remapped at address 0x0000 0000, only the first two regions of Bank 1 memory controller (Bank1 NOR/PSRAM 1 and NOR/PSRAM 2) can be remapped. In remap mode, the CPU can access the external memory via ICode bus instead of System bus which boosts up the performance.

Address offset: 0x00

Reset value: 0x0000 000X (X is the memory mode selected by the BOOT pins)

|          |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18       | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2        | 1  | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    | MEM_MODE |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    | rw       | rw |    |

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **MEM\_MODE**: Memory mapping selection

Set and cleared by software. This bit controls the memory internal mapping at address 0x0000 0000. After reset these bits take the value selected by the Boot pins (except for FSMC).

00: Main Flash memory mapped at 0x0000 0000

01: System Flash memory mapped at 0x0000 0000

10: FSMC Bank1 (NOR/PSRAM 1 and 2) mapped at 0x0000 0000

11: Embedded SRAM (SRAM1) mapped at 0x0000 0000

*Note:* Refer to [Section 2.3: Memory map](#) for details about the memory mapping at address 0x0000 0000.

9.2.2 SYSCFG peripheral mode configuration register (SYSCFG\_PMC)

Address offset: 0x04

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |              |          |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|--------------|----------|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22       | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    | MII_RMII_SEL | Reserved |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    | rw           |          |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7            | 6        | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    |              |          |    |    |    |    |    |    |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **MII\_RMII\_SEL**: Ethernet PHY interface selection

Set and Cleared by software. These bits control the PHY interface for the Ethernet MAC.

0: MII interface is selected

1: RMII PHY interface is selected

*Note:* This configuration must be done while the MAC is under reset and before enabling the MAC clocks.

Bits 22:0 Reserved, must be kept at reset value.

### 9.2.3 SYSCFG external interrupt configuration register 1 (SYSCFG\_EXTICR1)

Address offset: 0x08

Reset value: 0x0000 0000

|            |    |    |    |            |    |    |    |            |    |    |    |            |    |    |    |
|------------|----|----|----|------------|----|----|----|------------|----|----|----|------------|----|----|----|
| 31         | 30 | 29 | 28 | 27         | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19         | 18 | 17 | 16 |
| Reserved   |    |    |    |            |    |    |    |            |    |    |    |            |    |    |    |
| 15         | 14 | 13 | 12 | 11         | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3          | 2  | 1  | 0  |
| EXTI3[3:0] |    |    |    | EXTI2[3:0] |    |    |    | EXTI1[3:0] |    |    |    | EXTI0[3:0] |    |    |    |
| rw         | rw | rw | rw | rw         | rw | rw | rw | rw         | rw | rw | rw | rw         | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 0 to 3)

These bits are written by software to select the source input for the EXTIx external interrupt.

0000: PA[x] pin

0001: PB[x] pin

0010: PC[x] pin

0011: PD[x] pin

0100: PE[x] pin

0101: PF[x] pin

0110: PG[x] pin

0111: PH[x] pin

1000: PI[x] pin

### 9.2.4 SYSCFG external interrupt configuration register 2 (SYSCFG\_EXTICR2)

Address offset: 0x0C

Reset value: 0x0000 0000

|            |    |    |    |            |    |    |    |            |    |    |    |            |    |    |    |
|------------|----|----|----|------------|----|----|----|------------|----|----|----|------------|----|----|----|
| 31         | 30 | 29 | 28 | 27         | 26 | 25 | 24 | 23         | 22 | 21 | 20 | 19         | 18 | 17 | 16 |
| Reserved   |    |    |    |            |    |    |    |            |    |    |    |            |    |    |    |
| 15         | 14 | 13 | 12 | 11         | 10 | 9  | 8  | 7          | 6  | 5  | 4  | 3          | 2  | 1  | 0  |
| EXTI7[3:0] |    |    |    | EXTI6[3:0] |    |    |    | EXTI5[3:0] |    |    |    | EXTI4[3:0] |    |    |    |
| rw         | rw | rw | rw | rw         | rw | rw | rw | rw         | rw | rw | rw | rw         | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **EXTIx[3:0]**: EXTI x configuration (x = 4 to 7)

These bits are written by software to select the source input for the EXTIx external interrupt.

0000: PA[x] pin

0001: PB[x] pin

0010: PC[x] pin

0011: PD[x] pin

0100: PE[x] pin

0101: PF[x] pin

0110: PG[x] pin

0111: PH[x] pin

1000: PI[x] pin

### 9.2.5 SYSCFG external interrupt configuration register 3 (SYSCFG\_EXTICR3)

Address offset: 0x10

Reset value: 0x0000 0000

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 9.3 SYSCFG registers for STM32F42xxx and STM32F43xxx

### 9.3.1 SYSCFG memory remap register (SYSCFG\_MEMRMP)

This register is used for specific configurations on memory remap:

- Three bits are used to configure the type of memory accessible at address 0x0000 0000. These bits are used to select the physical remap by software and so, bypass the BOOT pins.
- After reset these bits take the value selected by the BOOT pins. When booting from main Flash memory with BOOT pins set to 10 [(BOOT1,BOOT0) = (1,0)] this register takes the value 0x00.
- Other bits are used to swap FMC SDRAM Bank 1/2 with FMC Bank 3/4 and configure the Flash Bank 1/2 mapping

There are two possible FMC remap at address 0x0000 0000:

- FMC Bank 1 (NOR/PSRAM 1 and 2) remap:  
Only the first two regions of Bank 1 memory controller (Bank1 NOR/PSRAM 1 and NOR/PSRAM 2) can be remapped.
- FMC SDRAM Bank 1 remap.

In remap mode at address 0x0000 0000, the CPU can access the external memory via ICode bus instead of System bus which boosts up the performance.

Address offset: 0x00

Reset value: 0x0000 000X (X is the memory mode selected by the BOOT pins)

**Note:** *Booting from NOR Flash memory or SDRAM is not allowed. The regions can only be mapped at 0x0000 0000 through software remap.*

|          |    |    |    |         |    |      |         |          |    |    |    |    |               |    |    |
|----------|----|----|----|---------|----|------|---------|----------|----|----|----|----|---------------|----|----|
| 31       | 30 | 29 | 28 | 27      | 26 | 25   | 24      | 23       | 22 | 21 | 20 | 19 | 18            | 17 | 16 |
| Reserved |    |    |    |         |    |      |         |          |    |    |    |    |               |    |    |
| 15       | 14 | 13 | 12 | 11      | 10 | 9    | 8       | 7        | 6  | 5  | 4  | 3  | 2             | 1  | 0  |
| Reserved |    |    |    | SWP_FMC |    | Res. | FB_MODE | Reserved |    |    |    |    | MEM_MODE[2:0] |    |    |
|          |    |    |    | rw      | rw |      |         |          |    |    |    |    | rw            | rw | rw |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:10 **SWP\_FMC**: FMC memory mapping swap

Set and cleared by software. These bits are used to swap the FMC SDRAM Bank 1/2 and FMC Bank 3/4 (SDRAM Bank 1/2 and NAND Bank 2/PCCARD Bank) in order to enable the code execution from SDRAM Banks without a physical remapping at 0x0000 0000 address.

00: No FMC memory mapping swap

01: SDRAM banks and NAND Bank 2/PCCARD mapping are swapped. SDRAM Bank 1 and 2 are mapped at NAND Bank 2 (0x8000 0000) and PCCARD Bank (0x9000 0000) address, respectively. NAND Bank 2 and PCCARD Bank are mapped at 0xC000 0000 and 0xD000 0000, respectively.

10: Reserved

11: Reserved

Bit 9 Reserved, must be kept at reset value.

Bit 8 **FB\_MODE**: Flash Bank mode selection

Set and cleared by software. This bit controls the Flash Bank 1/2 mapping.

0: Flash Bank 1 is mapped at 0x0800 0000 (and aliased at 0x0000 0000) and Flash Bank 2 is mapped at 0x0810 0000 (and aliased at 0x0010 0000)

1: Flash Bank 2 is mapped at 0x0800 0000 (and aliased at 0x0000 0000) and Flash Bank 1 is mapped at 0x0810 0000 (and aliased at 0x0010 0000)

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MEM\_MODE**: Memory mapping selection

Set and cleared by software. This bit controls the memory internal mapping at address 0x0000 0000. After reset these bits take the value selected by the Boot pins (except for FMC).

000: Main Flash memory mapped at 0x0000 0000

001: System Flash memory mapped at 0x0000 0000

010: FMC Bank1 (NOR/PSRAM 1 and 2) mapped at 0x0000 0000

011: Embedded SRAM (SRAM1) mapped at 0x0000 0000

100: FMC/SDRAM Bank 1 mapped at 0x0000 0000

Other configurations are reserved

*Note: Refer to [Section 2.3: Memory map](#) for details about the memory mapping at address 0x0000 0000.*

### 9.3.2 SYSCFG peripheral mode configuration register (SYSCFG\_PMC)

Address offset: 0x04

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |              |          |    |    |    |         |    |    |
|----------|----|----|----|----|----|----|----|--------------|----------|----|----|----|---------|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23           | 22       | 21 | 20 | 19 | 18      | 17 | 16 |
| Reserved |    |    |    |    |    |    |    | MII_RMII_SEL | Reserved |    |    |    | ADCxDC2 |    |    |
|          |    |    |    |    |    |    |    | rw           |          |    |    |    | rw      | rw | rw |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7            | 6        | 5  | 4  | 3  | 2       | 1  | 0  |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **MII\_RMII\_SEL**: Ethernet PHY interface selection

Set and Cleared by software. These bits control the PHY interface for the Ethernet MAC.

0: MII interface is selected

1: RMII PHY interface is selected

*Note: This configuration must be done while the MAC is under reset and before enabling the MAC clocks.*

Bits 22:19 Reserved, must be kept at reset value.

Bits 18:16 **ADCxDC2**:

0: No effect.

1: Refer to AN4073 on how to use this bit.

*Note: These bits can be set only if the following conditions are met:*

- ADC clock higher or equal to 30 MHz.
- Only one ADCxDC2 bit must be selected if ADC conversions do not start at the same time and the sampling times differ.
- These bits must not be set when the ADCDC1 bit is set in PWR\_CR register.

Bits 15:0 Reserved, must be kept at reset value.

### 9.3.3 SYSCFG external interrupt configuration register 1 (SYSCFG\_EXTICR1)

Address offset: 0x08

Reset value: 0x0000 0000

|            |    |    |    |            |    |    |    |            |    |    |    |            |    |    |    |
|------------|----|----|----|------------|----|----|----|------------|----|----|----|------------|----|----|----|

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 10 DMA controller (DMA)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 10.1 DMA introduction

Direct memory access (DMA) is used in order to provide high-speed data transfer between peripherals and memory and between memory and memory. Data can be quickly moved by DMA without any CPU action. This keeps CPU resources free for other operations.

The DMA controller combines a powerful dual AHB master bus architecture with independent FIFO to optimize the bandwidth of the system, based on a complex bus matrix architecture.

The two DMA controllers have 16 streams in total (8 for each controller), each dedicated to managing memory access requests from one or more peripherals. Each stream can have up to 8 channels (requests) in total. And each has an arbiter for handling the priority between DMA requests.

### 10.2 DMA main features

The main DMA features are:

- Dual AHB master bus architecture, one dedicated to memory accesses and one dedicated to peripheral accesses
  - AHB slave programming interface supporting only 32-bit accesses
  - 8 streams for each DMA controller, up to 8 channels (requests) per stream
  - Four-word depth 32 first-in, first-out memory buffers (FIFOs) per stream, that can be used in FIFO mode or direct mode:
    - FIFO mode: with threshold level software selectable between 1/4, 1/2 or 3/4 of the FIFO size
    - Direct mode
- Each DMA request immediately initiates a transfer from/to the memory. When it is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads only one data from the memory to the internal

FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.

- Each stream can be configured by hardware to be:
  - a regular channel that supports peripheral-to-memory, memory-to-peripheral and memory-to-memory transfers
  - a double buffer channel that also supports double buffering on the memory side
- Each of the 8 streams are connected to dedicated hardware DMA channels (requests)
- Priorities between DMA stream requests are software-programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (request 0 has priority over request 1, etc.)
- Each stream also supports software trigger for memory-to-memory transfers (only available for the DMA2 controller)
- Each stream request can be selected among up to 8 possible channel requests. This selection is software-configurable and allows several peripherals to initiate DMA requests
- The number of data items to be transferred can be managed either by the DMA controller or by the peripheral:
  - DMA flow controller: the number of data items to be transferred is software-programmable from 1 to 65535
  - Peripheral flow controller: the number of data items to be transferred is unknown and controlled by the source or the destination peripheral that signals the end of the transfer by hardware
- Independent source and destination transfer width (byte, half-word, word): when the data widths of the source and destination are not equal, the DMA automatically packs/unpacks the necessary transfers to optimize the bandwidth. This feature is only available in FIFO mode
- Incrementing or non-incrementing addressing for source and destination
- Supports incremental burst transfers of 4, 8 or 16 beats. The size of the burst is software-configurable, usually equal to half the FIFO size of the peripheral
- Each stream supports circular buffer management
- 5 event flags (DMA Half Transfer, DMA Transfer complete, DMA Transfer Error, DMA FIFO Error, Direct Mode Error) logically ORed together in a single interrupt request for each stream

## 10.3 DMA functional description

### 10.3.1 General description

Figure 32 shows the block diagram of a DMA.

Figure 32. DMA block diagram

The DMA controller performs direct memory transfer: as an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

It can carry out the following transactions:

- peripheral-to-memory
- memory-to-peripheral
- memory-to-memory

The DMA controller provides two AHB master ports: the *AHB memory port*, intended to be connected to memories and the *AHB peripheral port*, intended to be connected to peripherals. However, to allow memory-to-memory transfers, the *AHB peripheral port* must also have access to the memories.

The AHB slave port is used to program the DMA controller (it supports only 32-bit accesses).

See [Figure 33](#) and [Figure 34](#) for the implementation of the system of two DMA controllers.

**Figure 33. System implementation of the two DMA controllers  
(STM32F405xx/07xx and STM32F415xx/17xx)**

1. The DMA1 controller AHB peripheral port is not connected to the bus matrix like DMA2 controller. As a result, only DMA2 streams are able to perform memory-to-memory transfers.

**Figure 34. System implementation of the two DMA controllers (STM32F42xxx and STM32F43xxx)**

1. The DMA1 controller AHB peripheral port is not connected to the bus matrix like in the case of the DMA2 controller, thus only DMA2 streams are able to perform memory-to-memory transfers.

### 10.3.2 DMA transactions

A DMA transaction consists of a sequence of a given number of data transfers. The number of data items to be transferred and their width (8-bit, 16-bit or 32-bit) are software-programmable.

Each DMA transfer consists of three operations:

- A loading from the peripheral data register or a location in memory, addressed through the DMA\_SxPAR or DMA\_SxM0AR register
- A storage of the data loaded to the peripheral data register or a location in memory addressed through the DMA\_SxPAR or DMA\_SxM0AR register
- A post-decrement of the DMA\_SxNDTR register, which contains the number of transactions that still have to be performed

After an event, the peripheral sends a request signal to the DMA controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA controller accesses the peripheral, an Acknowledge signal is sent to the peripheral by the DMA controller. The peripheral releases its request as soon as it gets the Acknowledge signal from the DMA controller. Once the request has been deasserted by the peripheral, the DMA controller releases the Acknowledge signal. If there are more requests, the peripheral can initiate the next transaction.

### 10.3.3 Channel selection

Each stream is associated with a DMA request that can be selected out of 8 possible channel requests. The selection is controlled by the CHSEL[2:0] bits in the DMA\_SxCR register.

**Figure 35. Channel selection**

The 8 requests from the peripherals (TIM, ADC, SPI, I2C, etc.) are independently connected to each channel and their connection depends on the product implementation.

See the following table(s) for examples of DMA request mappings.

**Table 42. DMA1 request mapping**

| Peripheral requests | Stream 0                | Stream 1                | Stream 2            | Stream 3                | Stream 4              | Stream 5    | Stream 6                | Stream 7            |
|---------------------|-------------------------|-------------------------|---------------------|-------------------------|-----------------------|-------------|-------------------------|---------------------|
| Channel 0           | SPI3_RX                 | -                       | SPI3_RX             | SPI2_RX                 | SPI2_TX               | SPI3_TX     | -                       | SPI3_TX             |
| Channel 1           | I2C1_RX                 | -                       | TIM7_UP             | -                       | TIM7_UP               | I2C1_RX     | I2C1_TX                 | I2C1_TX             |
| Channel 2           | TIM4_CH1                | -                       | I2S3_EXT_RX         | TIM4_CH2                | I2S2_EXT_TX           | I2S3_EXT_TX | TIM4_UP                 | TIM4_CH3            |
| Channel 3           | I2S3_EXT_RX             | TIM2_UP<br>TIM2_CH3     | I2C3_RX             | I2S2_EXT_RX             | I2C3_TX               | TIM2_CH1    | TIM2_CH2<br>TIM2_CH4    | TIM2_UP<br>TIM2_CH4 |
| Channel 4           | UART5_RX                | USART3_RX               | UART4_RX            | USART3_TX               | UART4_TX              | USART2_RX   | USART2_TX               | UART5_TX            |
| Channel 5           | UART8_TX <sup>(1)</sup> | UART7_TX <sup>(1)</sup> | TIM3_CH4<br>TIM3_UP | UART7_RX <sup>(1)</sup> | TIM3_CH1<br>TIM3_TRIG | TIM3_CH2    | UART8_RX <sup>(1)</sup> | TIM3_CH3            |

Table 42. DMA1 request mapping (continued)

| Peripheral requests | Stream 0            | Stream 1              | Stream 2 | Stream 3              | Stream 4  | Stream 5 | Stream 6 | Stream 7 |

| Channel 6           | TIM1_TRIG              | TIM1_CH1               | TIM1_CH2                         | TIM1_CH1               | TIM1_CH4<br>TIM1_TRIG<br>TIM1_COM | TIM1_UP                | TIM1_CH3                         | -                                 |
| Channel 7           | -                      | TIM8_UP                | TIM8_CH1                         | TIM8_CH2               | TIM8_CH3                          | SPI5_RX <sup>(1)</sup> | SPI5_TX <sup>(1)</sup>           | TIM8_CH4<br>TIM8_TRIG<br>TIM8_COM |

1. These requests are available on STM32F42xxx and STM32F43xxx.

### 10.3.4 Arbiter

An arbiter manages the 8 DMA stream requests based on their priority for each of the two AHB master ports (memory and peripheral ports) and launches the peripheral/memory access sequences.

Priorities are managed in two stages:

- Software: each stream priority can be configured in the DMA\_SxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: If two requests have the same software priority level, the stream with the lower number takes priority over the stream with the higher number. For example, Stream 2 takes priority over Stream 4.

### 10.3.5 DMA streams

Each of the 8 DMA controller streams provides a unidirectional transfer link between a source and a destination.

Each stream can be configured to perform:

- Regular type transactions: memory-to-peripherals, peripherals-to-memory or memory-to-memory transfers
- Double-buffer type transactions: double buffer transfers using two memory pointers for the memory (while the DMA is reading/writing from/to a buffer, the application can write/read to/from the other buffer).

The amount of data to be transferred (up to 65535) is programmable and related to the source width of the peripheral that requests the DMA transfer connected to the peripheral AHB port. The register that contains the amount of data items to be transferred is decremented after each transaction.

### 10.3.6 Source, destination and transfer modes

Both source and destination transfers can address peripherals and memories in the entire 4 GB area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The direction is configured using the DIR[1:0] bits in the DMA\_SxCR register and offers three possibilities: memory-to-peripheral, peripheral-to-memory or memory-to-memory transfers. [Table 44](#) describes the corresponding source and destination addresses.

**Table 44. Source and destination address**

| Bits DIR[1:0] of the DMA_SxCR register | Direction            | Source address | Destination address |
|----------------------------------------|----------------------|----------------|---------------------|
| 00                                     | Peripheral-to-memory | DMA_SxPAR      | DMA_SxM0AR          |
| 01                                     | Memory-to-peripheral | DMA_SxM0AR     | DMA_SxPAR           |
| 10                                     | Memory-to-memory     | DMA_SxPAR      | DMA_SxM0AR          |
| 11                                     | reserved             | -              | -                   |

When the data width (programmed in the PSIZE or MSIZE bits in the DMA\_SxCR register) is a half-word or a word, respectively, the peripheral or memory address written into the DMA\_SxPAR or DMA\_SxM0AR/M1AR registers has to be aligned on a word or half-word address boundary, respectively.

#### Peripheral-to-memory mode

[Figure 36](#) describes this mode.

When this mode is enabled (by setting the bit EN in the DMA\_SxCR register), each time a peripheral request occurs, the stream initiates a transfer from the source to fill the FIFO.

When the threshold level of the FIFO is reached, the contents of the FIFO are drained and stored into the destination.

The transfer stops once the DMA\_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA\_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA\_SxFCR register is '0'), the threshold level of the FIFO is not used: after each single data transfer from the peripheral to the FIFO, the corresponding data are immediately drained and stored into the destination.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

**Figure 36. Peripheral-to-memory mode**

1. For double-buffer mode.

### Memory-to-peripheral mode

*Figure 37* describes this mode.

When this mode is enabled (by setting the EN bit in the DMA\_SxCR register), the stream immediately initiates transfers from the source to entirely fill the FIFO.

Each time a peripheral request occurs, the contents of the FIFO are drained and stored into the destination. When the level of the FIFO is lower than or equal to the predefined threshold level, the FIFO is fully reloaded with data from the memory.

The transfer stops once the DMA\_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA\_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA\_SxFCR register is '0'), the threshold level of the FIFO is not used. Once the stream is enabled, the DMA preloads the first data to transfer into an internal FIFO. As soon as the peripheral requests a data transfer, the DMA transfers the preloaded value into the configured destination. It then reloads again the

empty internal FIFO with the next data to be transfer. The preloaded data size corresponds to the value of the PSIZE bitfield in the DMA\_SxCR register.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

**Figure 37. Memory-to-peripheral mode**

1. For double-buffer mode.

### Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This is the memory-to-memory mode, described in [Figure 38](#).

When the stream is enabled by setting the Enable bit (EN) in the DMA\_SxCR register, the stream immediately starts to fill the FIFO up to the threshold level. When the threshold level is reached, the FIFO contents are drained and stored into the destination.

The transfer stops once the DMA\_SxNDTR register reaches zero or when the EN bit in the DMA\_SxCR register is cleared by software.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA\_SxCR register.

**Note:** *When memory-to-memory mode is used, the Circular and direct modes are not allowed. Only the DMA2 controller is able to perform memory-to-memory transfers.*

Figure 38. Memory-to-memory mode

1. For double-buffer mode.

### 10.3.7 Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented or kept constant after each transfer depending on the PINC and MINC bits in the DMA\_SxCR register.

Disabling the Increment mode is useful when the peripheral source or destination data are accessed through a single register.

If the Increment mode is enabled, the address of the next transfer will be the address of the previous one incremented by 1 (for bytes), 2 (for half-words) or 4 (for words) depending on the data width programmed in the PSIZE or MSIZE bits in the DMA\_SxCR register.

In order to optimize the packing operation, it is possible to fix the increment offset size for the peripheral address whatever the size of the data transferred on the AHB peripheral port. The PINCOS bit in the DMA\_SxCR register is used to align the increment offset size with the data size on the peripheral AHB port, or on a 32-bit address (the address is then incremented by 4). The PINCOS bit has an impact on the AHB peripheral port only.

If PINCOS bit is set, the address of the next transfer is the address of the previous one incremented by 4 (automatically aligned on a 32-bit address) whatever the PSIZE value. The AHB memory port, however, is not impacted by this operation.

### 10.3.8 Circular mode

The Circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA\_SxCR register.

When the circular mode is activated, the number of data items to be transferred is automatically reloaded with the initial value programmed during the stream configuration phase, and the DMA requests continue to be served.

**Note:** *In the circular mode, it is mandatory to respect the following rule in case of a burst mode configured for memory:*

*DMA\_SxNDTR = Multiple of  $((\text{Mburst beat}) \times (\text{Msize})/(\text{Psize}))$ , where:*

- *(Mburst beat) = 4, 8 or 16 (depending on the MBURST bits in the DMA\_SxCR register)*
- *$((\text{Msize})/(\text{Psize})) = 1, 2, 4, 1/2 \text{ or } 1/4$  (Msize and Psize represent the MSIZE and PSIZE bits in the DMA\_SxCR register. They are byte dependent)*
- *DMA\_SxNDTR = Number of data items to transfer on the AHB peripheral port*

*For example: Mburst beat = 8 (INCR8), MSIZE = '00' (byte) and PSIZE = '01' (half-word), in this case: DMA\_SxNDTR must be a multiple of  $(8 \times 1/2 = 4)$ .*

*If this formula is not respected, the DMA behavior and data integrity are not guaranteed.*

*NDTR must also be a multiple of the Peripheral burst size multiplied by the peripheral data size, otherwise this could result in a bad DMA behavior.*

### 10.3.9 Double buffer mode

This mode is available for all the DMA1 and DMA2 streams.

The Double buffer mode is enabled by setting the DBM bit in the DMA\_SxCR register.

A double-buffer stream works as a regular (single buffer) stream with the difference that it has two memory pointers. When the Double buffer mode is enabled, the Circular mode is automatically enabled (CIRC bit in DMA\_SxCR is don't care) and at each end of transaction, the memory pointers are swapped.

In this mode, the DMA controller swaps from one memory target to another at each end of transaction. This allows the software to process one memory area while the second memory area is being filled/used by the DMA transfer. The double-buffer stream can work in both directions (the memory can be either the source or the destination) as described in [Table 45: Source and destination address registers in Double buffer mode \(DBM=1\)](#).

**Note:** *In Double buffer mode, it is possible to update the base address for the AHB memory port on-the-fly (DMA\_SxM0AR or DMA\_SxM1AR) when the stream is enabled, by respecting the following conditions:*

- *When the CT bit is '0' in the DMA\_SxCR register, the DMA\_SxM1AR register can be written. Attempting to write to this register while CT = '1' sets an error flag (TEIF) and the stream is automatically disabled.*
- *When the CT bit is '1' in the DMA\_SxCR register, the DMA\_SxM0AR register can be written. Attempting to write to this register while CT = '0', sets an error flag (TEIF) and the stream is automatically disabled.*

*To avoid any error condition, it is advised to change the base address as soon as the TCIF flag is asserted because, at this point, the targeted memory must have changed from*

memory 0 to 1 (or from 1 to 0) depending on the value of CT in the DMA\_SxCR register in accordance with one of the two above conditions.

For all the other modes (except the Double buffer mode), the memory address registers are write-protected as soon as the stream is enabled.

**Table 45. Source and destination address registers in Double buffer mode (DBM=1)**

| Bits DIR[1:0] of the DMA_SxCR register | Direction                  | Source address          | Destination address     |
|----------------------------------------|----------------------------|-------------------------|-------------------------|
| 00                                     | Peripheral-to-memory       | DMA_SxPAR               | DMA_SxM0AR / DMA_SxM1AR |
| 01                                     | Memory-to-peripheral       | DMA_SxM0AR / DMA_SxM1AR | DMA_SxPAR               |
| 10                                     | Not allowed <sup>(1)</sup> |                         |                         |
| 11                                     | Reserved                   | -                       | -                       |

1. When the Double buffer mode is enabled, the Circular mode is automatically enabled. Since the memory-to-memory mode is not compatible with the Circular mode, when the Double buffer mode is enabled, it is not allowed to configure the memory-to-memory mode.

### 10.3.10 Programmable data width, packing/unpacking, endianness

The number of data items to be transferred has to be programmed into DMA\_SxNDTR (number of data items to transfer bit, NDT) before enabling the stream (except when the flow controller is the peripheral, PFCTRL bit in DMA\_SxCR is set).

When using the internal FIFO, the data widths of the source and destination data are programmable through the PSIZE and MSIZE bits in the DMA\_SxCR register (can be 8-, 16- or 32-bit).

When PSIZE and MSIZE are not equal:

- The data width of the number of data items to transfer, configured in the DMA\_SxNDTR register is equal to the width of the peripheral bus (configured by the PSIZE bits in the DMA\_SxCR register). For instance, in case of peripheral-to-memory, memory-to-peripheral or memory-to-memory transfers and if the PSIZE[1:0] bits are configured for half-word, the number of bytes to be transferred is equal to  $2 \times \text{NDT}$ .
- The DMA controller only copes with little-endian addressing for both source and destination. This is described in [Table 46: Packing/unpacking & endian behavior \(bit PINC = MINC = 1\)](#).

This packing/unpacking procedure may present a risk of data corruption when the operation is interrupted before the data are completely packed/unpacked. So, to ensure data coherence, the stream may be configured to generate burst transfers: in this case, each group of transfers belonging to a burst are indivisible (refer to [Section 10.3.11: Single and burst transfers](#)).

In direct mode (DMDIS = 0 in the DMA\_SxFCR register), the packing/unpacking of data is not possible. In this case, it is not allowed to have different source and destination transfer data widths: both are equal and defined by the PSIZE bits in the DMA\_SxCR MSIZE bits are don't care).

Table 46. Packing/unpacking &amp; endian behavior (bit PINC = MINC = 1)

| AHB memory port width | AHB peripheral port width | Number of data items to transfer (NDT) | Memory transfer number | Memory port address / byte lane | Peripheral transfer number | Peripheral port address / byte lane |                         |
|-----------------------|---------------------------|----------------------------------------|------------------------|---------------------------------|----------------------------|-------------------------------------|-------------------------|

| 32                    | 32                        | 1                                      | 1                      | 0x0 / B3 B2 B1 B0 [31:0]        | 1                          | 0x0 / B3 B2 B1 B0 [31:0]            | 0x0 / B3 B2 B1 B0[31:0] |

**Note:** Peripheral port may be the source or the destination (it could also be the memory source in the case of memory-to-memory transfer).

PSIZE, MSIZE and NDT[15:0] have to be configured so as to ensure that the last transfer will not be incomplete. This can occur when the data width of the peripheral port (PSIZE bits) is lower than the data width of the memory port (MSIZE bits). This constraint is summarized in [Table 47](#).

Table 47. Restriction on NDT versus PSIZE and MSIZE

| PSIZE[1:0] of DMA_SxCR | MSIZE[1:0] of DMA_SxCR | NDT[15:0] of DMA_SxNDTR |
|------------------------|------------------------|-------------------------|
| 00 (8-bit)             | 01 (16-bit)            | must be a multiple of 2 |
| 00 (8-bit)             | 10 (32-bit)            | must be a multiple of 4 |
| 01 (16-bit)            | 10 (32-bit)            | must be a multiple of 2 |

### 10.3.11 Single and burst transfers

The DMA controller can generate single transfers or incremental burst transfers of 4, 8 or 16 beats.

The size of the burst is configured by software independently for the two AHB ports by using the MBURST[1:0] and PBURST[1:0] bits in the DMA\_SxCR register.

The burst size indicates the number of beats in the burst, not the number of bytes transferred.

To ensure data coherence, each group of transfers that form a burst are indivisible: AHB transfers are locked and the arbiter of the AHB bus matrix does not degrant the DMA master during the sequence of the burst transfer.

Depending on the single or burst configuration, each DMA request initiates a different number of transfers on the AHB peripheral port:

- When the AHB peripheral port is configured for single transfers, each DMA request generates a data transfer of a byte, half-word or word depending on the PSIZE[1:0] bits in the DMA\_SxCR register
- When the AHB peripheral port is configured for burst transfers, each DMA request generates 4, 8 or 16 beats of byte, half word or word transfers depending on the PBURST[1:0] and PSIZE[1:0] bits in the DMA\_SxCR register.

The same as above has to be considered for the AHB memory port considering the MBURST and MSIZE bits.

In direct mode, the stream can only generate single transfers and the MBURST[1:0] and PBURST[1:0] bits are forced by hardware.

The address pointers (DMA\_SxPAR or DMA\_SxM0AR registers) must be chosen so as to ensure that all transfers within a burst block are aligned on the address boundary equal to the size of the transfer.

The burst configuration has to be selected in order to respect the AHB protocol, where bursts must *not* cross the 1 KB address boundary because the minimum address space that can be allocated to a single slave is 1 KB. This means that the 1 KB address boundary should not be crossed by a burst block transfer, otherwise an AHB error would be generated, that is not reported by the DMA registers.

### 10.3.12 FIFO

#### FIFO structure

The FIFO is used to temporarily store data coming from the source before transmitting them to the destination.

Each stream has an independent 4-word FIFO and the threshold level is software-configurable between 1/4, 1/2, 3/4 or full.

To enable the use of the FIFO threshold level, the direct mode must be disabled by setting the DMDIS bit in the DMA\_SxFCR register.

The structure of the FIFO differs depending on the source and destination data widths, and is described in [Figure 39: FIFO structure](#).

Figure 39. FIFO structure

### FIFO threshold and burst configuration

Caution is required when choosing the FIFO threshold (bits FTH[1:0] of the DMA\_SxFCR register) and the size of the memory burst (MBURST[1:0] of the DMA\_SxCR register): The content pointed by the FIFO threshold must exactly match to an integer number of memory burst transfers. If this is not in the case, a FIFO error (flag FEIFx of the DMA\_HISR or DMA\_LISR register) will be generated when the stream is enabled, then the stream will be automatically disabled. The allowed and forbidden configurations are described in the [Table 48: FIFO threshold configurations](#).

**Table 48. FIFO threshold configurations**

| MSIZE     | FIFO level | MBURST = INCR4      | MBURST = INCR8      | MBURST = INCR16     |
|-----------|------------|---------------------|---------------------|---------------------|
| Byte      | 1/4        | 1 burst of 4 beats  | forbidden           | forbidden           |
|           | 1/2        | 2 bursts of 4 beats | 1 burst of 8 beats  |                     |
|           | 3/4        | 3 bursts of 4 beats | forbidden           |                     |
|           | Full       | 4 bursts of 4 beats | 2 bursts of 8 beats | 1 burst of 16 beats |
| Half-word | 1/4        | forbidden           | forbidden           | forbidden           |
|           | 1/2        | 1 burst of 4 beats  |                     |                     |
|           | 3/4        | forbidden           |                     |                     |
|           | Full       | 2 bursts of 4 beats | 1 burst of 8 beats  |                     |
| Word      | 1/4        | forbidden           | forbidden           |                     |
|           | 1/2        |                     |                     |                     |
|           | 3/4        |                     |                     |                     |
|           | Full       | 1 burst of 4 beats  |                     |                     |

In all cases, the burst size multiplied by the data size must not exceed the FIFO size (data size can be: 1 (byte), 2 (half-word) or 4 (word)).

Incomplete Burst transfer at the end of a DMA transfer may happen if one of the following conditions occurs:

- For the AHB peripheral port configuration: the total number of data items (set in the DMA\_SxNDTR register) is not a multiple of the burst size multiplied by the data size
- For the AHB memory port configuration: the number of remaining data items in the FIFO to be transferred to the memory is not a multiple of the burst size multiplied by the data size

In such cases, the remaining data to be transferred will be managed in single mode by the DMA, even if a burst transaction was requested during the DMA stream configuration.

**Note:** *When burst transfers are requested on the peripheral AHB port and the FIFO is used (DMDIS = 1 in the DMA\_SxCR register), it is mandatory to respect the following rule to avoid permanent underrun or overrun conditions, depending on the DMA stream direction:*

*If  $(PBURST \times PSIZE) = FIFO\_SIZE$  (4 words),  $FIFO\_Threshold = 3/4$  is forbidden with  $PSIZE = 1, 2$  or  $4$  and  $PBURST = 4, 8$  or  $16$ .*

*This rule ensures that enough FIFO space at a time will be free to serve the request from the peripheral.*

### FIFO flush

The FIFO can be flushed when the stream is disabled by resetting the EN bit in the DMA\_SxCR register and when the stream is configured to manage peripheral-to-memory or memory-to-memory transfers: If some data are still present in the FIFO when the stream is disabled, the DMA controller continues transferring the remaining data to the destination (even though stream is effectively disabled). When this flush is completed, the transfer complete status bit (TCIFx) in the DMA\_LISR or DMA\_HISR register is set.

The remaining data counter DMA\_SxNDTR keeps the value in this case to indicate how many data items are currently available in the destination memory.

Note that during the FIFO flush operation, if the number of remaining data items in the FIFO to be transferred to memory (in bytes) is less than the memory data width (for example 2 bytes in FIFO while MSIZE is configured to word), data will be sent with the data width set in the MSIZE bit in the DMA\_SxCR register. This means that memory will be written with an undesired value. The software may read the DMA\_SxNDTR register to determine the memory area that contains the good data (start address and last address).

If the number of remaining data items in the FIFO is lower than a burst size (if the MBURST bits in DMA\_SxCR register are set to configure the stream to manage burst on the AHB memory port), single transactions will be generated to complete the FIFO flush.

### Direct mode

By default, the FIFO operates in direct mode (DMDIS bit in the DMA\_SxFCR is reset) and the FIFO threshold level is not used. This mode is useful when the system requires an immediate and single transfer to or from the memory after each DMA request.

When the DMA is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.

To avoid saturating the FIFO, it is recommended to configure the corresponding stream with a high priority.

This mode is restricted to transfers where:

- The source and destination transfer widths are equal and both defined by the PSIZE[1:0] bits in DMA\_SxCR (MSIZE[1:0] bits are don't care)
- Burst transfers are not possible (PBURST[1:0] and MBURST[1:0] bits in DMA\_SxCR are don't care)

Direct mode must not be used when implementing memory-to-memory transfers.

## 10.3.13 DMA transfer completion

Different events can generate an end of transfer by setting the TCIFx bit in the DMA\_LISR or DMA\_HISR status register:

- In DMA flow controller mode:
  - The DMA\_SxNDTR counter has reached zero in the memory-to-peripheral mode
  - The stream is disabled before the end of transfer (by clearing the EN bit in the DMA\_SxCR register) and (when transfers are peripheral-to-memory or memory-

to-memory) all the remaining data have been flushed from the FIFO into the memory

- In Peripheral flow controller mode:
  - The last external burst or single request has been generated from the peripheral and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory
  - The stream is disabled by software, and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory

*Note:* The transfer completion is dependent on the remaining data in FIFO to be transferred into memory only in the case of peripheral-to-memory mode. This condition is not applicable in memory-to-peripheral mode.

If the stream is configured in noncircular mode, after the end of the transfer (that is when the number of data to be transferred reaches zero), the DMA is stopped (EN bit in DMA\_SxCR register is cleared by Hardware) and no DMA request is served unless the software reprograms the stream and re-enables it (by setting the EN bit in the DMA\_SxCR register).

### 10.3.14 DMA transfer suspension

At any time, a DMA transfer can be suspended to be restarted later on or to be definitively disabled before the end of the DMA transfer.

There are two cases:

- The stream disables the transfer with no later-on restart from the point where it was stopped. There is no particular action to do, except to clear the EN bit in the DMA\_SxCR register to disable the stream. The stream may take time to be disabled (ongoing transfer is completed first). The transfer complete interrupt flag (TCIF in the DMA\_LISR or DMA\_HISR register) is set in order to indicate the end of transfer. The value of the EN bit in DMA\_SxCR is now '0' to confirm the stream interruption. The DMA\_SxNDTR register contains the number of remaining data items at the moment when the stream was stopped so that the software can determine how many data items have been transferred before the stream was interrupted.
- The stream suspends the transfer before the number of remaining data items to be transferred in the DMA\_SxNDTR register reaches 0. The aim is to restart the transfer later by re-enabling the stream. In order to restart from the point where the transfer was stopped, the software has to read the DMA\_SxNDTR register after disabling the stream by writing the EN bit in DMA\_SxCR register (and then checking that it is at '0') to know the number of data items already collected. Then:
  - The peripheral and/or memory addresses have to be updated in order to adjust the address pointers
  - The SxNDTR register has to be updated with the remaining number of data items to be transferred (the value read when the stream was disabled)
  - The stream may then be re-enabled to restart the transfer from the point it was stopped

*Note:* Note that a Transfer complete interrupt flag (TCIF in DMA\_LISR or DMA\_HISR) is set to indicate the end of transfer due to the stream interruption.

### 10.3.15 Flow controller

The entity that controls the number of data to be transferred is known as the flow controller. This flow controller is configured independently for each stream using the PFCTRL bit in the DMA\_SxCR register.

The flow controller can be:

- The DMA controller: in this case, the number of data items to be transferred is programmed by software into the DMA\_SxNDTR register before the DMA stream is enabled.
- The peripheral source or destination: this is the case when the number of data items to be transferred is unknown. The peripheral indicates by hardware to the DMA controller when the last data are being transferred. This feature is only supported for peripherals which are able to signal the end of the transfer, that is:
  - SDIO

When the peripheral flow controller is used for a given stream, the value written into the DMA\_SxNDTR has no effect on the DMA transfer. Actually, whatever the value written, it will be forced by hardware to 0xFFFF as soon as the stream is enabled, to respect the following schemes:

- Anticipated stream interruption: EN bit in DMA\_SxCR register is reset to 0 by the software to stop the stream before the last data hardware signal (single or burst) is sent by the peripheral. In such a case, the stream is switched off and the FIFO flush is triggered in the case of a peripheral-to-memory DMA transfer. The TCIFx flag of the corresponding stream is set in the status register to indicate the DMA completion. To know the number of data items transferred during the DMA transfer, read the DMA\_SxNDTR register and apply the following formula:
  - $\text{Number\_of\_data\_transferred} = 0xFFFF - \text{DMA\_SxNDTR}$
- Normal stream interruption due to the reception of a last data hardware signal: the stream is automatically interrupted when the peripheral requests the last transfer (single or burst) and when this transfer is complete. the TCIFx flag of the corresponding stream is set in the status register to indicate the DMA transfer completion. To know the number of data items transferred, read the DMA\_SxNDTR register and apply the same formula as above.
- The DMA\_SxNDTR register reaches 0: the TCIFx flag of the corresponding stream is set in the status register to indicate the forced DMA transfer completion. The stream is automatically switched off even though the last data hardware signal (single or burst) has not been yet asserted. The already transferred data will not be lost. This means that a maximum of 65535 data items can be managed by the DMA in a single transaction, even in peripheral flow control mode.

*Note:* When configured in memory-to-memory mode, the DMA is always the flow controller and the PFCTRL bit is forced to 0 by hardware.

*The Circular mode is forbidden in the peripheral flow controller mode.*

### 10.3.16 Summary of the possible DMA configurations

Table 49 summarizes the different possible DMA configurations.

**Table 49. Possible DMA configurations**

| DMA transfer mode    | Source              | Destination         | Flow controller | Circular mode | Transfer type | Direct mode | Double buffer mode |
|----------------------|---------------------|---------------------|-----------------|---------------|---------------|-------------|--------------------|
| Peripheral-to-memory | AHB peripheral port | AHB memory port     | DMA             | possible      | single        | possible    | possible           |
|                      |                     |                     |                 |               | burst         | forbidden   |                    |
|                      |                     |                     | Peripheral      | forbidden     | single        | possible    | forbidden          |
|                      |                     |                     |                 |               | burst         | forbidden   |                    |
| Memory-to-peripheral | AHB memory port     | AHB peripheral port | DMA             | possible      | single        | possible    | possible           |
|                      |                     |                     |                 |               | burst         | forbidden   |                    |
|                      |                     |                     | Peripheral      | forbidden     | single        | possible    | forbidden          |
|                      |                     |                     |                 |               | burst         | forbidden   |                    |
| Memory-to-memory     | AHB peripheral port | AHB memory port     | DMA only        | forbidden     | single        | forbidden   | forbidden          |
|                      |                     |                     |                 |               | burst         |             |                    |

### 10.3.17 Stream configuration procedure

The following sequence should be followed to configure a DMA stream x (where x is the stream number):

1. If the stream is enabled, disable it by resetting the EN bit in the DMA\_SxCR register, then read this bit in order to confirm that there is no ongoing stream operation. Writing this bit to 0 is not immediately effective since it is actually written to 0 once all the current transfers have finished. When the EN bit is read as 0, this means that the stream is ready to be configured. It is therefore necessary to wait for the EN bit to be cleared before starting any stream configuration. All the stream dedicated bits set in the status register (DMA\_LISR and DMA\_HISR) from the previous data block DMA transfer should be cleared before the stream can be re-enabled.
2. Set the peripheral port register address in the DMA\_SxPAR register. The data will be moved from/ to this address to/ from the peripheral port after the peripheral event.
3. Set the memory address in the DMA\_SxMA0R register (and in the DMA\_SxMA1R register in the case of a double buffer mode). The data will be written to or read from this memory after the peripheral event.
4. Configure the total number of data items to be transferred in the DMA\_SxNDTR register. After each peripheral event or each beat of the burst, this value is decremented.
5. Select the DMA channel (request) using CHSEL[2:0] in the DMA\_SxCR register.
6. If the peripheral is intended to be the flow controller and if it supports this feature, set the PFCTRL bit in the DMA\_SxCR register.
7. Configure the stream priority using the PL[1:0] bits in the DMA\_SxCR register.
8. Configure the FIFO usage (enable or disable, threshold in transmission and reception)
9. Configure the data transfer direction, peripheral and memory incremented/fixed mode, single or burst transactions, peripheral and memory data widths, Circular mode,

Double buffer mode and interrupts after half and/or full transfer, and/or errors in the DMA\_SxCR register.

10. Activate the stream by setting the EN bit in the DMA\_SxCR register.

As soon as the stream is enabled, it can serve any DMA request from the peripheral connected to the stream.

Once half the data have been transferred on the AHB destination port, the half-transfer flag (HTIF) is set and an interrupt is generated if the half-transfer interrupt enable bit (HTIE) is set. At the end of the transfer, the transfer complete flag (TCIF) is set and an interrupt is generated if the transfer complete interrupt enable bit (TCIE) is set.

---

**Warning:** To switch off a peripheral connected to a DMA stream request, it is mandatory to, first, switch off the DMA stream to which the peripheral is connected, then to wait for EN bit = 0. Only then can the peripheral be safely disabled.

---

### 10.3.18 Error management

The DMA controller can detect the following errors:

- **Transfer error:** the transfer error interrupt flag (TEIFx) is set when:
  - A bus error occurs during a DMA read or a write access
  - A write access is requested by software on a memory address register in Double buffer mode whereas the stream is enabled and the current target memory is the one impacted by the write into the memory address register (refer to [Section 10.3.9: Double buffer mode](#))
- **FIFO error:** the FIFO error interrupt flag (FEIFx) is set if:
  - A FIFO underrun condition is detected
  - A FIFO overrun condition is detected (no detection in memory-to-memory mode because requests and transfers are internally managed by the DMA)
  - The stream is enabled while the FIFO threshold level is not compatible with the size of the memory burst (refer to [Table 48: FIFO threshold configurations](#))
- **Direct mode error:** the direct mode error interrupt flag (DMEIFx) can only be set in the peripheral-to-memory mode while operating in direct mode and when the MINC bit in the DMA\_SxCR register is cleared. This flag is set when a DMA request occurs while the previous data have not yet been fully transferred into the memory (because the memory bus was not granted). In this case, the flag indicates that 2 data items were be transferred successively to the same destination address, which could be an issue if the destination is not able to manage this situation

In direct mode, the FIFO error flag can also be set under the following conditions:

- In the peripheral-to-memory mode, the FIFO can be saturated (overrun) if the memory bus is not granted for several peripheral requests
- In the memory-to-peripheral mode, an underrun condition may occur if the memory bus has not been granted before a peripheral request occurs

If the TEIFx or the FEIFx flag is set due to incompatibility between burst size and FIFO threshold level, the faulty stream is automatically disabled through a hardware clear of its EN bit in the corresponding stream configuration register (DMA\_SxCR).

If the DMEIFx or the FEIFx flag is set due to an overrun or underrun condition, the faulty stream is not automatically disabled and it is up to the software to disable or not the stream by resetting the EN bit in the DMA\_SxCR register. This is because there is no data loss when this kind of errors occur.

When the stream's error interrupt flag (TEIF, FEIF, DMEIF) in the DMA\_LISR or DMA\_HISR register is set, an interrupt is generated if the corresponding interrupt enable bit (TEIE, FEIE, DMIE) in the DMA\_SxCR or DMA\_SxFCR register is set.

**Note:** *When a FIFO overrun or underrun condition occurs, the data are not lost because the peripheral request is not acknowledged by the stream until the overrun or underrun condition is cleared. If this acknowledge takes too much time, the peripheral itself may detect an overrun or underrun condition of its internal buffer and data might be lost.*

## 10.4 DMA interrupts

For each DMA stream, an interrupt can be produced on the following events:

- Half-transfer reached
- Transfer complete
- Transfer error
- Fifo error (overrun, underrun or FIFO level error)
- Direct mode error

Separate interrupt enable control bits are available for flexibility as shown in [Table 50](#).

**Table 50. DMA interrupt requests**

| Interrupt event       | Event flag | Enable control bit |
|-----------------------|------------|--------------------|
| Half-transfer         | HTIF       | HTIE               |
| Transfer complete     | TCIF       | TCIE               |
| Transfer error        | TEIF       | TEIE               |
| FIFO overrun/underrun | FEIF       | FEIE               |
| Direct mode error     | DMEIF      | DMEIE              |

**Note:** *Before setting an Enable control bit to '1', the corresponding event flag should be cleared, otherwise an interrupt is immediately generated.*

## 10.5 DMA registers

The DMA registers have to be accessed by words (32 bits).

### 10.5.1 DMA low interrupt status register (DMA\_LISR)

Address offset: 0x00

Reset value: 0x0000 0000

| 31       | 30 | 29 | 28 | 27    | 26    | 25    | 24     | 23           | 22    | 21    | 20    | 19    | 18     | 17           | 16    |
|----------|----|----|----|-------|-------|-------|--------|--------------|-------|-------|-------|-------|--------|--------------|-------|
| Reserved |    |    |    | TCIF3 | HTIF3 | TEIF3 | DMEIF3 | Reserv<br>ed | FEIF3 | TCIF2 | HTIF2 | TEIF2 | DMEIF2 | Reserv<br>ed | FEIF2 |
| r        | r  | r  | r  | r     | r     | r     | r      |              | r     | r     | r     | r     | r      |              | r     |
| 15       | 14 | 13 | 12 | 11    | 10    | 9     | 8      | 7            | 6     | 5     | 4     | 3     | 2      | 1            | 0     |
| Reserved |    |    |    | TCIF1 | HTIF1 | TEIF1 | DMEIF1 | Reserv<br>ed | FEIF1 | TCIF0 | HTIF0 | TEIF0 | DMEIF0 | Reserv<br>ed | FEIF0 |
| r        | r  | r  | r  | r     | r     | r     | r      |              | r     | r     | r     | r     | r      |              | r     |

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIFx**: Stream x transfer complete interrupt flag (x = 3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No transfer complete event on stream x

1: A transfer complete event occurred on stream x

Bits 26, 20, 10, 4 **HTIFx**: Stream x half transfer interrupt flag (x=3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No half transfer event on stream x

1: A half transfer event occurred on stream x

Bits 25, 19, 9, 3 **TEIFx**: Stream x transfer error interrupt flag (x=3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No transfer error on stream x

1: A transfer error occurred on stream x

Bits 24, 18, 8, 2 **DMEIFx**: Stream x direct mode error interrupt flag (x=3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No Direct Mode Error on stream x

1: A Direct Mode Error occurred on stream x

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIFx**: Stream x FIFO error interrupt flag (x=3..0)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_LIFCR register.

0: No FIFO Error event on stream x

1: A FIFO Error event occurred on stream x

### 10.5.2 DMA high interrupt status register (DMA\_HISR)

Address offset: 0x04

Reset value: 0x0000 0000

|          |    |    |    |       |       |       |        |          |       |       |       |       |        |          |       |
|----------|----|----|----|-------|-------|-------|--------|----------|-------|-------|-------|-------|--------|----------|-------|
| 31       | 30 | 29 | 28 | 27    | 26    | 25    | 24     | 23       | 22    | 21    | 20    | 19    | 18     | 17       | 16    |
| Reserved |    |    |    | TCIF7 | HTIF7 | TEIF7 | DMEIF7 | Reserved | FEIF7 | TCIF6 | HTIF6 | TEIF6 | DMEIF6 | Reserved | FEIF6 |
|          |    |    |    | r     | r     | r     | r      |          | r     | r     | r     | r     | r      |          | r     |
| 15       | 14 | 13 | 12 | 11    | 10    | 9     | 8      | 7        | 6     | 5     | 4     | 3     | 2      | 1        | 0     |
| Reserved |    |    |    | TCIF5 | HTIF5 | TEIF5 | DMEIF5 | Reserved | FEIF5 | TCIF4 | HTIF4 | TEIF4 | DMEIF4 | Reserved | FEIF4 |
|          |    |    |    | r     | r     | r     | r      |          | r     | r     | r     | r     | r      |          | r     |

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIFx**: Stream x transfer complete interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No transfer complete event on stream x

1: A transfer complete event occurred on stream x

Bits 26, 20, 10, 4 **HTIFx**: Stream x half transfer interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No half transfer event on stream x

1: A half transfer event occurred on stream x

Bits 25, 19, 9, 3 **TEIFx**: Stream x transfer error interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No transfer error on stream x

1: A transfer error occurred on stream x

Bits 24, 18, 8, 2 **DMEIFx**: Stream x direct mode error interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No Direct mode error on stream x

1: A Direct mode error occurred on stream x

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIFx**: Stream x FIFO error interrupt flag (x=7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA\_HIFCR register.

0: No FIFO error event on stream x

1: A FIFO error event occurred on stream x

### 10.5.3 DMA low interrupt flag clear register (DMA\_LIFCR)

Address offset: 0x08

Reset value: 0x0000 0000

|          |    |    |    |        |        |        |         |          |        |        |        |        |         |          |        |
|----------|----|----|----|--------|--------|--------|---------|----------|--------|--------|--------|--------|---------|----------|--------|
| 31       | 30 | 29 | 28 | 27     | 26     | 25     | 24      | 23       | 22     | 21     | 20     | 19     | 18      | 17       | 16     |
| Reserved |    |    |    | CTCIF3 | CHTIF3 | CTEIF3 | CDMEIF3 | Reserved | CFEIF3 | CTCIF2 | CHTIF2 | CTEIF2 | CDMEIF2 | Reserved | CFEIF2 |
|          |    |    |    | w      | w      | w      | w       |          | w      | w      | w      | w      | w       |          | w      |
| 15       | 14 | 13 | 12 | 11     | 10     | 9      | 8       | 7        | 6      | 5      | 4      | 3      | 2       | 1        | 0      |
| Reserved |    |    |    | CTCIF1 | CHTIF1 | CTEIF1 | CDMEIF1 | Reserved | CFEIF1 | CTCIF0 | CHTIF0 | CTEIF0 | CDMEIF0 | Reserved | CFEIF0 |
|          |    |    |    | w      | w      | w      | w       |          | w      | w      | w      | w      | w       |          | w      |

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIFx**: Stream x clear transfer complete interrupt flag (x = 3..0)

Writing 1 to this bit clears the corresponding TCIFx flag in the DMA\_LISR register

Bits 26, 20, 10, 4 **CHTIFx**: Stream x clear half transfer interrupt flag (x = 3..0)

Writing 1 to this bit clears the corresponding HTIFx flag in the DMA\_LISR register

Bits 25, 19, 9, 3 **CTEIFx**: Stream x clear transfer error interrupt flag (x = 3..0)

Writing 1 to this bit clears the corresponding TEIFx flag in the DMA\_LISR register

Bits 24, 18, 8, 2 **CDMEIFx**: Stream x clear direct mode error interrupt flag (x = 3..0)

Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA\_LISR register

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIFx**: Stream x clear FIFO error interrupt flag (x = 3..0)

Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA\_LISR register

### 10.5.4 DMA high interrupt flag clear register (DMA\_HIFCR)

Address offset: 0x0C

Reset value: 0x0000 0000

|          |    |    |    |        |        |        |         |          |        |        |        |        |         |          |        |
|----------|----|----|----|--------|--------|--------|---------|----------|--------|--------|--------|--------|---------|----------|--------|
| 31       | 30 | 29 | 28 | 27     | 26     | 25     | 24      | 23       | 22     | 21     | 20     | 19     | 18      | 17       | 16     |
| Reserved |    |    |    | CTCIF7 | CHTIF7 | CTEIF7 | CDMEIF7 | Reserved | CFEIF7 | CTCIF6 | CHTIF6 | CTEIF6 | CDMEIF6 | Reserved | CFEIF6 |
|          |    |    |    | w      | w      | w      | w       |          | w      | w      | w      | w      | w       |          | w      |
| 15       | 14 | 13 | 12 | 11     | 10     | 9      | 8       | 7        | 6      | 5      | 4      | 3      | 2       | 1        | 0      |
| Reserved |    |    |    | CTCIF5 | CHTIF5 | CTEIF5 | CDMEIF5 | Reserved | CFEIF5 | CTCIF4 | CHTIF4 | CTEIF4 | CDMEIF4 | Reserved | CFEIF4 |
|          |    |    |    | w      | w      | w      | w       |          | w      | w      | w      | w      | w       |          | w      |

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIFx**: Stream x clear transfer complete interrupt flag (x = 7..4)

Writing 1 to this bit clears the corresponding TCIFx flag in the DMA\_HISR register

Bits 26, 20, 10, 4 **CHTIFx**: Stream x clear half transfer interrupt flag (x = 7..4)

Writing 1 to this bit clears the corresponding HTIFx flag in the DMA\_HISR register

Bits 25, 19, 9, 3 **CTEIFx**: Stream x clear transfer error interrupt flag (x = 7..4)

Writing 1 to this bit clears the corresponding TEIFx flag in the DMA\_HISR register

Bits 24, 18, 8, 2 **CDMEIFx**: Stream x clear direct mode error interrupt flag (x = 7..4)

Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA\_HISR register

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIFx**: Stream x clear FIFO error interrupt flag (x = 7..4)

Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA\_HISR register

### 10.5.5 DMA stream x configuration register (DMA\_SxCR) (x = 0..7)

This register is used to configure the concerned stream.

Address offset:  $0x10 + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

|          |            |    |            |            |      |      |              |          |             |        |          |      |      |         |    |
|----------|------------|----|------------|------------|------|------|--------------|----------|-------------|--------|----------|------|------|---------|----|
| 31       | 30         | 29 | 28         | 27         | 26   | 25   | 24           | 23       | 22          | 21     | 20       | 19   | 18   | 17      | 16 |

| 15       | 14         | 13 | 12         | 11         | 10   | 9    | 8            | 7        | 6           | 5      | 4        | 3    | 2    | 1       | 0  |
| PINCOS   | MSIZE[1:0] |    | PSIZE[1:0] |            | MINC | PINC | CIRC         | DIR[1:0] |             | PFCTRL | TCIE     | HTIE | TEIE | DMEIE   | EN |
| rw       | rw         | rw | rw         | rw         | rw   | rw   | rw           | rw       | rw          | rw     | rw       | rw   | rw   | rw      | rw |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:25 **CHSEL[2:0]**: Channel selection

These bits are set and cleared by software.

000: channel 0 selected

001: channel 1 selected

010: channel 2 selected

011: channel 3 selected

100: channel 4 selected

101: channel 5 selected

110: channel 6 selected

111: channel 7 selected

These bits are protected and can be written only if EN is '0'

Bits 24:23 **MBURST**: Memory burst transfer configuration

These bits are set and cleared by software.

00: single transfer

01: INCR4 (incremental burst of 4 beats)

10: INCR8 (incremental burst of 8 beats)

11: INCR16 (incremental burst of 16 beats)

These bits are protected and can be written only if EN is '0'

In direct mode, these bits are forced to 0x0 by hardware as soon as bit EN= '1'.

Bits 22:21 **PBURST[1:0]**: Peripheral burst transfer configuration

These bits are set and cleared by software.

00: single transfer

01: INCR4 (incremental burst of 4 beats)

10: INCR8 (incremental burst of 8 beats)

11: INCR16 (incremental burst of 16 beats)

These bits are protected and can be written only if EN is '0'

In direct mode, these bits are forced to 0x0 by hardware.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CT**: Current target (only in double buffer mode)

This bit is set and cleared by hardware. It can also be written by software.

0: The current target memory is Memory 0 (addressed by the DMA\_SxM0AR pointer)

1: The current target memory is Memory 1 (addressed by the DMA\_SxM1AR pointer)

This bit can be written only if EN is '0' to indicate the target memory area of the first transfer.

Once the stream is enabled, this bit operates as a status flag indicating which memory area is the current target.

Bit 18 **DBM**: Double buffer mode

This bit is set and cleared by software.

0: No buffer switching at the end of transfer

1: Memory target switched at the end of the DMA transfer

This bit is protected and can be written only if EN is '0'.

Bits 17:16 **PL[1:0]**: Priority level

These bits are set and cleared by software.

00: Low

01: Medium

10: High

11: Very high

These bits are protected and can be written only if EN is '0'.

Bit 15 **PINCOS**: Peripheral increment offset size

This bit is set and cleared by software

0: The offset size for the peripheral address calculation is linked to the PSIZE

1: The offset size for the peripheral address calculation is fixed to 4 (32-bit alignment).

This bit has no meaning if bit PINC = '0'.

This bit is protected and can be written only if EN = '0'.

This bit is forced low by hardware when the stream is enabled (bit EN = '1') if the direct mode is selected or if PBURST are different from "00".

Bits 14:13 **MSIZE[1:0]**: Memory data size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: reserved

These bits are protected and can be written only if EN is '0'.

In direct mode, MSIZE is forced by hardware to the same value as PSIZE as soon as bit EN = '1'.

Bits 12:11 **PSIZE[1:0]**: Peripheral data size

These bits are set and cleared by software.

00: Byte (8-bit)

01: Half-word (16-bit)

10: Word (32-bit)

11: reserved

These bits are protected and can be written only if EN is '0'.

Bit 10 **MINC**: Memory increment mode

This bit is set and cleared by software.

0: Memory address pointer is fixed

1: Memory address pointer is incremented after each data transfer (increment is done according to MSIZE)

This bit is protected and can be written only if EN is '0'.

**Bit 9 PINC:** Peripheral increment mode

This bit is set and cleared by software.

0: Peripheral address pointer is fixed

1: Peripheral address pointer is incremented after each data transfer (increment is done according to PSIZE)

This bit is protected and can be written only if EN is '0'.

**Bit 8 CIRC:** Circular mode

This bit is set and cleared by software and can be cleared by hardware.

0: Circular mode disabled

1: Circular mode enabled

When the peripheral is the flow controller (bit PFCTRL=1) and the stream is enabled (bit EN=1), then this bit is automatically forced by hardware to 0.

It is automatically forced by hardware to 1 if the DBM bit is set, as soon as the stream is enabled (bit EN = '1').

**Bits 7:6 DIR[1:0]:** Data transfer direction

These bits are set and cleared by software.

00: Peripheral-to-memory

01: Memory-to-peripheral

10: Memory-to-memory

11: reserved

These bits are protected and can be written only if EN is '0'.

**Bit 5 PFCTRL:** Peripheral flow controller

This bit is set and cleared by software.

0: The DMA is the flow controller

1: The peripheral is the flow controller

This bit is protected and can be written only if EN is '0'.

When the memory-to-memory mode is selected (bits DIR[1:0]=10), then this bit is automatically forced to 0 by hardware.

**Bit 4 TCIE:** Transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disabled

1: TC interrupt enabled

**Bit 3 HTIE:** Half transfer interrupt enable

This bit is set and cleared by software.

0: HT interrupt disabled

1: HT interrupt enabled

**Bit 2 TEIE:** Transfer error interrupt enable

This bit is set and cleared by software.

0: TE interrupt disabled

1: TE interrupt enabled

**Bit 1 DMEIE:** Direct mode error interrupt enable

This bit is set and cleared by software.

0: DME interrupt disabled

1: DME interrupt enabled

Bit 0 **EN**: Stream enable / flag stream ready when read low

This bit is set and cleared by software.

0: Stream disabled

1: Stream enabled

This bit may be cleared by hardware:

- on a DMA end of transfer (stream ready to be configured)
- if a transfer error occurs on the AHB master buses
- when the FIFO threshold on memory AHB port is not compatible with the size of the burst

When this bit is read as 0, the software is allowed to program the Configuration and FIFO bits registers. It is forbidden to write these registers when the EN bit is read as 1.

*Note: Before setting EN bit to '1' to start a new transfer, the event flags corresponding to the stream in DMA\_LISR or DMA\_HISR register must be cleared.*

## 10.5.6 DMA stream x number of data register (DMA\_SxNDTR) (x = 0..7)

Address offset:  $0x14 + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| NDT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: Number of data items to transfer

Number of data items to be transferred (0 up to 65535). This register can be written only when the stream is disabled. When the stream is enabled, this register is read-only, indicating the remaining data items to be transmitted. This register decrements after each DMA transfer.

Once the transfer has completed, this register can either stay at zero (when the stream is in normal mode) or be reloaded automatically with the previously programmed value in the following cases:

- when the stream is configured in Circular mode.
- when the stream is enabled again by setting EN bit to '1'

If the value of this register is zero, no transaction can be served even if the stream is enabled.

### 10.5.7 DMA stream x peripheral address register (DMA\_SxPAR) (x = 0..7)

Address offset:  $0x18 + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| PAR[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PAR[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **PAR[31:0]**: Peripheral address

Base address of the peripheral data register from/to which the data will be read/written.

These bits are write-protected and can be written only when bit EN = '0' in the DMA\_SxCR register.

### 10.5.8 DMA stream x memory 0 address register (DMA\_SxM0AR) (x = 0..7)

Address offset:  $0x1C + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| M0A[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| M0A[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **M0A[31:0]**: Memory 0 address

Base address of Memory area 0 from/to which the data will be read/written.

These bits are write-protected. They can be written only if:

- the stream is disabled (bit EN = '0' in the DMA\_SxCR register) or
- the stream is enabled (EN = '1' in DMA\_SxCR register) and bit CT = '1' in the DMA\_SxCR register (in Double buffer mode).

### 10.5.9 DMA stream x memory 1 address register (DMA\_SxM1AR) (x = 0..7)

Address offset:  $0x20 + 0x18 \times \text{stream number}$

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| M1A[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

| M1A[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **M1A[31:0]**: Memory 1 address (used in case of Double buffer mode)

Base address of Memory area 1 from/to which the data will be read/written.

This register is used only for the Double buffer mode.

These bits are write-protected. They can be written only if:

- the stream is disabled (bit EN= '0' in the DMA\_SxCR register) or
- the stream is enabled (EN='1' in DMA\_SxCR register) and bit CT = '0' in the DMA\_SxCR register.

### 10.5.10 DMA stream x FIFO control register (DMA\_SxFCR) (x = 0..7)

Address offset:  $0x24 + 0x24 \times \text{stream number}$

Reset value: 0x0000 0021

|          |    |    |    |    |    |    |    |      |          |         |    |    |       |          |    |
|----------|----|----|----|----|----|----|----|------|----------|---------|----|----|-------|----------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22       | 21      | 20 | 19 | 18    | 17       | 16 |
| Reserved |    |    |    |    |    |    |    |      |          |         |    |    |       |          |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7    | 6        | 5       | 4  | 3  | 2     | 1        | 0  |
| Reserved |    |    |    |    |    |    |    | FEIE | Reserved | FS[2:0] |    |    | DMDIS | FTH[1:0] |    |
|          |    |    |    |    |    |    |    | rw   |          | r       | r  | r  | rw    | rw       | rw |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **FEIE**: FIFO error interrupt enable

This bit is set and cleared by software.

0: FE interrupt disabled

1: FE interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bits 5:3 **FS[2:0]**: FIFO status

These bits are read-only.

000:  $0 < \text{fifo\_level} < 1/4$

001:  $1/4 \leq \text{fifo\_level} < 1/2$

010:  $1/2 \leq \text{fifo\_level} < 3/4$

011:  $3/4 \leq \text{fifo\_level} < \text{full}$

100: FIFO is empty

101: FIFO is full

others: no meaning

These bits are not relevant in the direct mode (DMDIS bit is zero).

Bit 2 **DMDIS**: Direct mode disable

This bit is set and cleared by software. It can be set by hardware.

0: Direct mode enabled

1: Direct mode disabled

This bit is protected and can be written only if EN is '0'.

This bit is set by hardware if the memory-to-memory mode is selected (DIR bit in DMA\_SxCR are "10") and the EN bit in the DMA\_SxCR register is '1' because the direct mode is not allowed in the memory-to-memory configuration.

Bits 1:0 **FTH[1:0]**: FIFO threshold selection

These bits are set and cleared by software.

00: 1/4 full FIFO

01: 1/2 full FIFO

10: 3/4 full FIFO

11: full FIFO

These bits are not used in the direct mode when the DMIS value is zero.

These bits are protected and can be written only if EN is '0'.

## 10.5.11 DMA register map

Table 51 summarizes the DMA registers.

Table 51. DMA register map and reset values

| Offset | Register    | 31        | 30 | 29 | 28 | 27         | 26     | 25          | 24      | 23          | 22     | 21       | 20     | 19     | 18      | 17       | 16       | 15         | 14 | 13         | 12 | 11  | 10     | 9      | 8        | 7        | 6        | 5      | 4      | 3      | 2        | 1       | 0        |        |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 11 Chrom-Art Accelerator™ controller (DMA2D)

### 11.1 DMA2D introduction

The Chrom-Art Accelerator™ (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format.

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

## 11.2 DMA2D main features

The main DMA2D features are:

- Single AHB master bus architecture.
- AHB slave programming interface supporting 8/16/32-bit accesses (except for CLUT accesses which are 32-bit).
- User programmable working area size
- User programmable offset for sources and destination areas
- User programmable sources and destination addresses on the whole memory space
- Up to 2 sources with blending operation
- Alpha value can be modified (source value, fixed value or modulated value)
- User programmable source and destination color format
- Up to 11 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AHB bandwidth
- 4 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, and memory-to-memory with pixel format conversion and blending
- Area filling with a fixed color
- Copy from an area to another
- Copy with pixel format conversion between source and destination images
- Copy from two sources with independent color format and blending
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

## 11.3 DMA2D functional description

### 11.3.1 General description

The DMA2D controller performs direct memory transfer. As an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

The DMA2D can operate in the following modes:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with Pixel Format Conversion
- Memory-to-memory with Pixel Format Conversion and Blending

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in [Figure 40: DMA2D block diagram](#).

Figure 40. DMA2D block diagram

### 11.3.2 DMA2D control

The DMA2D controller is configured through the DMA2D Control Register (DMA2D\_CR) which allows selecting:

The user application can perform the following operations:

- Select the operating mode
- Enable/disable the DMA2D interrupt
- Start/suspend/abort ongoing data transfers

### 11.3.3 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through a set of control registers:

- DMA2D foreground memory address register (DMA2D\_FGMAR)
- DMA2D foreground offset register (DMA2D\_FGOR)
- DMA2D background memory address register (DMA2D\_BGMAR)
- DMA2D background offset register (DMA2D\_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D\_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

#### 11.3.4 DMA2D foreground and background pixel format converter (PFC)

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first stage of the converter converts the color format. The original color format of the foreground pixel and background pixels are configured through the CM[3:0] bits of the DMA2D\_FGPFCCR and DMA2D\_BGPFCCR, respectively.

The supported input formats are given in [Table 52: Supported color mode in input](#).

**Table 52. Supported color mode in input**

| CM[3:0] | Color mode |
|---------|------------|
| 0000    | ARGB8888   |
| 0001    | RGB888     |
| 0010    | RGB565     |
| 0011    | ARGB1555   |
| 0100    | ARGB4444   |
| 0101    | L8         |
| 0110    | AL44       |
| 0111    | AL88       |
| 1000    | L4         |
| 1001    | A8         |
| 1010    | A4         |

The color format are coded as follows:

- Alpha value field: transparency  
0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance  
This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode, then the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode, a CLUT is required and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and is defined in the DMA2D\_FGCOLR for foreground pixels and in the DMA2D\_BGCOLR register for background pixels.

The order of the fields in the system memory is defined in [Table 53: Data order in memory](#).

**Table 53. Data order in memory**

| Color Mode | @ + 3                                                      | @ + 2                                    | @ + 1                                                      | @ + 0                                    |
|------------|------------------------------------------------------------|------------------------------------------|------------------------------------------------------------|------------------------------------------|
| ARGB8888   | A <sub>0</sub> [7:0]                                       | R <sub>0</sub> [7:0]                     | G <sub>0</sub> [7:0]                                       | B <sub>0</sub> [7:0]                     |
| RGB888     | B <sub>1</sub> [7:0]                                       | R <sub>0</sub> [7:0]                     | G <sub>0</sub> [7:0]                                       | B <sub>0</sub> [7:0]                     |
|            | G <sub>2</sub> [7:0]                                       | B <sub>2</sub> [7:0]                     | R <sub>1</sub> [7:0]                                       | G <sub>1</sub> [7:0]                     |
|            | R <sub>3</sub> [7:0]                                       | G <sub>3</sub> [7:0]                     | B <sub>3</sub> [7:0]                                       | R <sub>2</sub> [7:0]                     |
| RGB565     | R <sub>1</sub> [4:0]G <sub>1</sub> [5:3]                   | G <sub>1</sub> [2:0]B <sub>1</sub> [4:0] | R <sub>0</sub> [4:0]G <sub>0</sub> [5:3]                   | G <sub>0</sub> [2:0]B <sub>0</sub> [4:0] |
| ARGB1555   | A <sub>1</sub> [0]R <sub>1</sub> [4:0]G <sub>1</sub> [4:3] | G <sub>1</sub> [2:0]B <sub>1</sub> [4:0] | A <sub>0</sub> [0]R <sub>0</sub> [4:0]G <sub>0</sub> [4:3] | G <sub>0</sub> [2:0]B <sub>0</sub> [4:0] |
| ARGB4444   | A <sub>1</sub> [3:0]R <sub>1</sub> [3:0]                   | G <sub>1</sub> [3:0]B <sub>1</sub> [3:0] | A <sub>0</sub> [3:0]R <sub>0</sub> [3:0]                   | G <sub>0</sub> [3:0]B <sub>0</sub> [3:0] |
| L8         | L <sub>3</sub> [7:0]                                       | L <sub>2</sub> [7:0]                     | L <sub>1</sub> [7:0]                                       | L <sub>0</sub> [7:0]                     |
| AL44       | A <sub>3</sub> [3:0]L <sub>3</sub> [3:0]                   | A <sub>2</sub> [3:0]L <sub>2</sub> [3:0] | A <sub>1</sub> [3:0]L <sub>1</sub> [3:0]                   | A <sub>0</sub> [3:0]L <sub>0</sub> [3:0] |
| AL88       | A <sub>1</sub> [7:0]                                       | L <sub>1</sub> [7:0]                     | A <sub>0</sub> [7:0]                                       | L <sub>0</sub> [7:0]                     |
| L4         | L <sub>7</sub> [3:0]L <sub>6</sub> [3:0]                   | L <sub>5</sub> [3:0]L <sub>4</sub> [3:0] | L <sub>3</sub> [3:0]L <sub>2</sub> [3:0]                   | L <sub>1</sub> [3:0]L <sub>0</sub> [3:0] |
| A8         | A <sub>3</sub> [7:0]                                       | A <sub>2</sub> [7:0]                     | A <sub>1</sub> [7:0]                                       | A <sub>0</sub> [7:0]                     |
| A4         | A <sub>7</sub> [3:0]A <sub>6</sub> [3:0]                   | A <sub>5</sub> [3:0]A <sub>4</sub> [3:0] | A <sub>3</sub> [3:0]A <sub>2</sub> [3:0]                   | A <sub>1</sub> [3:0]A <sub>0</sub> [3:0] |

The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to the AM[1:0] field of the DMA2D\_FGPFCCR/DMA2D\_BGPFCCR registers as shown in [Table 54: Alpha mode configuration](#).

The alpha channel can be:

- kept as it is (no modification),
- replaced by the ALPHA[7:0] value of DMA2D\_FGPFCCR/DMA2D\_BGPFCCR,
- or replaced by the original alpha value multiplied by the ALPHA[7:0] value of DMA2D\_FGPFCCR/DMA2D\_BGPFCCR divided by 255.

**Table 54. Alpha mode configuration**

| AM[1:0] | Alpha mode                                                                |
|---------|---------------------------------------------------------------------------|
| 00      | No modification                                                           |
| 01      | Replaced by value in DMA2D_xxPFCCR                                        |
| 10      | Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255 |
| 11      | Reserved                                                                  |

### 11.3.5 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AHB master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading  
The following sequence should be followed to load the CLUT:
  - a) Program the CLUT address into the DMA2D\_FGCMAR register (foreground CLUT) or DMA2D\_BGCMAR register (background CLUT)
  - b) Program the CLUT size in the CS[7:0] field of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT).
  - c) Set the START bit of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE is set to '1' in DMA2D\_CR.
- Manual loading  
The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT is located at address offset 0x0400 and the background CLUT at address offset 0x0800.

The CLUT format can be 24 or 32 bits. It is configured through the CCM bit of the DMA2D\_FGPFCCR register (foreground CLUT) or DMA2D\_BGPFCCR register (background CLUT) as shown in [Table 55: Supported CLUT color mode](#).

Table 55. Supported CLUT color mode

| CCM | CLUT color mode |
|-----|-----------------|
| 0   | 32-bit ARGB8888 |
| 1   | 24-bit RGB888   |

The way the CLUT data are organized in the system memory is specified in [Table 56: CLUT data order in memory](#).

Table 56. CLUT data order in memory

| CLUT Color Mode | @ + 3                | @ + 2                | @ + 1                | @ + 0                |
|-----------------|----------------------|----------------------|----------------------|----------------------|
| ARGB8888        | A <sub>0</sub> [7:0] | R <sub>0</sub> [7:0] | G <sub>0</sub> [7:0] | B <sub>0</sub> [7:0] |
| RGB888          | B <sub>1</sub> [7:0] | R <sub>0</sub> [7:0] | G <sub>0</sub> [7:0] | B <sub>0</sub> [7:0] |
|                 | G <sub>2</sub> [7:0] | B <sub>2</sub> [7:0] | R <sub>1</sub> [7:0] | G <sub>1</sub> [7:0] |
|                 | R <sub>3</sub> [7:0] | G <sub>3</sub> [7:0] | B <sub>3</sub> [7:0] | R <sub>2</sub> [7:0] |

### 11.3.6 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.

The blending is performed according to the following equation:

$$\text{with } \alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}$$

$$\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}$$

$$C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B$$

*Division is rounded to the nearest lower integer*

No configuration register is required by the blender. The blender usage depends on the DMA2D operating mode defined in MODE[1:0] field of the DMA2D\_CR register.

### 11.3.7 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined in the CM[2:0] field of the DMA2D output pixel format converter configuration register (DMA2D\_OPFCCR).

The supported output formats are given in [Table 57: Supported color mode in output](#)

Table 57. Supported color mode in output

| CM[2:0] | Color mode |
|---------|------------|
| 000     | ARGB8888   |
| 001     | RGB888     |
| 010     | RGB565     |
| 011     | ARGB1555   |
| 100     | ARGB4444   |

### 11.3.8 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through a set of control registers:

- DMA2D output memory address register (DMA2D\_OMAR)
- DMA2D output offset register (DMA2D\_OOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D\_NLR)

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in the DMA2D output color register (DMA2D\_OCOLR) which contains a fixed 32-bit, 24-bit or 16-bit value. The format is selected by the CM[2:0] field of the DMA2D\_OPFCCR register.

The data are stored into the memory in the order defined in [Table 58: Data order in memory](#)

Table 58. Data order in memory

| Color Mode | @ + 3                                                      | @ + 2                                    | @ + 1                                                      | @ + 0                                    |
|------------|------------------------------------------------------------|------------------------------------------|------------------------------------------------------------|------------------------------------------|
| ARGB8888   | A <sub>0</sub> [7:0]                                       | R <sub>0</sub> [7:0]                     | G <sub>0</sub> [7:0]                                       | B <sub>0</sub> [7:0]                     |
| RGB888     | B <sub>1</sub> [7:0]                                       | R <sub>0</sub> [7:0]                     | G <sub>0</sub> [7:0]                                       | B <sub>0</sub> [7:0]                     |
|            | G <sub>2</sub> [7:0]                                       | B <sub>2</sub> [7:0]                     | R <sub>1</sub> [7:0]                                       | G <sub>1</sub> [7:0]                     |
|            | R <sub>3</sub> [7:0]                                       | G <sub>3</sub> [7:0]                     | B <sub>3</sub> [7:0]                                       | R <sub>2</sub> [7:0]                     |
| RGB565     | R <sub>1</sub> [4:0]G <sub>1</sub> [5:3]                   | G <sub>1</sub> [2:0]B <sub>1</sub> [4:0] | R <sub>0</sub> [4:0]G <sub>0</sub> [5:3]                   | G <sub>0</sub> [2:0]B <sub>0</sub> [4:0] |
| ARGB1555   | A <sub>1</sub> [0]R <sub>1</sub> [4:0]G <sub>1</sub> [4:3] | G <sub>1</sub> [2:0]B <sub>1</sub> [4:0] | A <sub>0</sub> [0]R <sub>0</sub> [4:0]G <sub>0</sub> [4:3] | G <sub>0</sub> [2:0]B <sub>0</sub> [4:0] |
| ARGB4444   | A <sub>1</sub> [3:0]R <sub>1</sub> [3:0]                   | G <sub>1</sub> [3:0]B <sub>1</sub> [3:0] | A <sub>0</sub> [3:0]R <sub>0</sub> [3:0]                   | G <sub>0</sub> [3:0]B <sub>0</sub> [3:0] |

The RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

### 11.3.9 DMA2D AHB master port timer

An 8-bit timer is embedded into the AHB master port to provide an optional limitation of the bandwidth on the crossbar.

This timer is clocked by the AHB clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and the dead time value are configured through the AHB master port timer configuration register (DMA2D\_AMPTCR).

### 11.3.10 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. The number of data and the width can be programmed by software.

Each DMA2D data transfer is composed of up to 4 steps:

1. Data loading from the memory location pointed by the DMA2D\_FGMAR register and pixel format conversion as defined in DMA2D\_FGCR.
2. Data loading from a memory location pointed by the DMA2D\_BGMAR register and pixel format conversion as defined in DMA2D\_BGCR.
3. Blending of all retrieved pixels according to the alpha channels resulting of the PFC operation on alpha values.
4. Pixel format conversion of the resulting pixels according to the DMA2D\_OCR register and programming of the data to the memory location addressed through the DMA2D\_OMAR register.

### 11.3.11 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4 Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the four following modes selected through MODE[1:0] bits of the DMA2D\_CR register:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending

#### Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color.

The color format is set in the DMA2D\_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in the DMA2D\_OCOLR register to the area located at the address pointed by the DMA2D\_OMAR and defined in the DMA2D\_NLR and DMA2D\_OOR.

#### Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer and the data are transferred from the source memory location defined in DMA2D\_FGMAR to the destination memory location pointed by DMA2D\_OMAR.

The color mode programmed in the CM[3:0] bits of the DMA2D\_FGPFCCR register defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by the DMA2D\_NLR and DMA2D\_FGOR registers for the source, and by DMA2D\_NLR and DMA2D\_OOR registers for the destination.

### Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data and stores them in the destination memory location.

The size of the areas to be transferred are defined by the DMA2D\_NLR and DMA2D\_FGOR registers for the source, and by DMA2D\_NLR and DMA2D\_OOR registers for the destination.

Data are fetched from the location defined in the DMA2D\_FGMAR register and processed by the foreground PFC. The original pixel format is configured through the DMA2D\_FGPFCCR register.

If the original pixel format is direct color mode, then the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into the DMA2D\_FGCMAR.
2. Set the CLUT size in the CS[7:0] bits of the DMA2D\_FGPFCCR register.
3. Set the CLUT format (24 or 32 bits) in the CCM bit of the DMA2D\_FGPFCCR register.
4. Start the CLUT loading by setting the START bit of the DMA2D\_FGPFCCR register.

Once the CLUT loading is complete, the CTCIF flag of the DMA2D\_IFR register is raised, and an interrupt is generated if the CTCIE bit is set in DMA2D\_CR. The automatic CLUT loading process can not work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the APB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in the DMA2D\_FGPFCCR register. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel. The alpha value can be modified according to the AM[1:0] bits of the DMA2D\_FGPFCCR register:

- It can be unchanged.
- It can be replaced by the value defined in the ALPHA[7:0] value of the DMA2D\_FGPFCCR register.
- It can be replaced by the original value multiplied by the ALPHA[7:0] value of the DMA2D\_FGPFCCR register divided by 255.

The resulting 32-bit data are encoded by the OUT PFC into the format specified by the CM[2:0] field of the DMA2D\_OPFCCR register. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

The processed data are written into the destination memory location pointed by DMA2D\_OMAR.

### Memory-to-memory with PFC and blending

In this mode, 2 sources are fetched in the foreground FIFO and background FIFO from the memory locations defined by DMA2D\_FGMAR and DMA2D\_BGMAR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended according to the equation below:

$$\text{with } \alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255}$$

$$\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}$$

$$C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B$$

*Division are rounded to the nearest lower integer*

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D\_OMAR.

### Configuration error detection

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if the CEIE bit of the DMA2D\_CR is set.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits of DMA2D\_FGCMAR not aligned with CCM of DMA2D\_FGPFCCR.
- Background CLUT automatic loading: MA of DMA2D\_BGCMAR not aligned with CCM of DMA2D\_BGPFCCR
- Memory transfer (except in register-to-memory mode): MA of DMA2D\_FGMAR not aligned with CM of DMA2D\_FGPFCCR
- Memory transfer (except in register-to-memory mode): CM in DMA2D\_FGPFCCR are invalid
- Memory transfer (except in register-to-memory mode): PL bits of DMA2D\_NLR odd while CM of DMA2D\_FGPFCCR is A4 or L4
- Memory transfer (except in register-to-memory mode): LO bits in DMA2D\_FGOR odd while CM of DMA2D\_FGPFCCR is A4 or L4
- Memory transfer (only in blending mode): MA bits in DMA2D\_BGMAR are not aligned with the CM of DMA2D\_BGPFCCR
- Memory transfer: CM of DMA2D\_BGPFCCR invalid (only in blending mode)
- Memory transfer (only in blending mode): PL bits of DMA2D\_NLR odd while CM of DMA2D\_BGPFCCR is A4 or L4
- Memory transfer (only in blending mode): LO bits of DMA2D\_BGOR odd while CM of DMA2D\_BGPFCCR is A4 or L4
- Memory transfer (except in memory to memory mode): MA bits in DMA2D\_OMAR are not aligned with CM bits in DMA2D\_OPFCCR.
- Memory transfer (except in memory to memory mode): CM bits in DMA2D\_OPFCCR invalid
- Memory transfer: NL bits in DMA2D\_NLR = 0
- Memory transfer: PL bits in DMA2D\_NLR = 0

### 11.3.12 DMA2D transfer control (start, suspend, abort and completion)

Once the DMA2D is configured, the transfer can be launched by setting the START bit of the DMA2D\_CR register. Once the transfer is completed, the START bit is automatically reset and the TCIF flag of the DMA2D\_ISR register is raised. An interrupt can be generated if the TCIE bit of the DMA2D\_CR is set.

The user application can suspend the DMA2D at any time by setting the SUSP bit of the DMA2D\_CR register. The transaction can then be aborted by setting the ABORT bit of the DMA2D\_CR register or can be restarted by resetting the SUSP bit of the DMA2D\_CR register.

The user application can abort at any time an ongoing transaction by setting the ABORT bit of the DMA2D\_CR register. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using the ABORT or the SUSP bit of the DMA2D\_CR register.

### 11.3.13 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in the LW[15:0] field of the DMA2D\_LWR register.

When the last pixel of this line has been transferred, the TWIF flag of the DMA2D\_ISR register is raised and an interrupt is generated if the TWIE bit of the DMA2D\_CR is set.

### 11.3.14 Error management

Two kind of errors can be triggered:

- AHB master port errors signalled by the TEIF flag of the DMA2D\_ISR register.
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signalled by the CAEIF flag of the DMA2D\_ISR register.

Both flags are associated to their own interrupt enable flag in the DMA2D\_CR register to generate an interrupt if need be (TEIE and CAEIE).

### 11.3.15 AHB dead time

To limit the AHB bandwidth usage, a dead time between two consecutive AHB accesses can be programmed.

This feature can be enabled by setting the EN bit in the DMA2D\_AMTCR register.

The dead time value is stored in the DT[7:0] field of the DMA2D\_AMTCR register. This value represents the guaranteed minimum number of cycles between two consecutive transactions on the AHB bus.

The update of the dead time value while the DMA2D is running will be taken into account for the next AHB transfer.

## 11.4 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

**Table 59. DMA2D interrupt requests**

| Interrupt event        | Event flag | Enable control bit |
|------------------------|------------|--------------------|
| Configuration error    | CEIF       | CEIE               |
| CLUT transfer complete | CTCIF      | CTCIE              |

Table 59. DMA2D interrupt requests (continued)

| Interrupt event    | Event flag | Enable control bit |
|--------------------|------------|--------------------|
| CLUT access error  | CAEIF      | CAEIE              |
| Transfer watermark | TWF        | TWIE               |
| Transfer complete  | TCIF       | TCIE               |
| Transfer error     | TEIF       | TEIE               |

## 11.5 DMA2D registers

### 11.5.1 DMA2D control register (DMA2D\_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

|          |    |      |       |       |      |      |      |          |    |    |    |    |    |       |      |       |
|----------|----|------|-------|-------|------|------|------|----------|----|----|----|----|----|-------|------|-------|
| 31       | 30 | 29   | 28    | 27    | 26   | 25   | 24   | 23       | 22 | 21 | 20 | 19 | 18 | 17    | 16   |       |
| Reserved |    |      |       |       |      |      |      |          |    |    |    |    |    | MODE  |      |       |
|          |    |      |       |       |      |      |      |          |    |    |    |    |    |       |      |       |
| 15       | 14 | 13   | 12    | 11    | 10   | 9    | 8    | 7        | 6  | 5  | 4  | 3  | 2  | 1     | 0    |       |
| Reserved |    | CEIE | CTCIE | CAEIE | TWIE | TCIE | TEIE | Reserved |    |    |    |    |    | ABORT | SUSP | START |
|          |    | rw   | rw    | rw    | rw   | rw   | rw   |          |    |    |    |    |    | rs    | rw   | rs    |

Bits 31:18 Reserved, must be kept at reset value

Bits 17:16 **MODE**: DMA2D mode

This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.

00: Memory-to-memory (FG fetch only)

01: Memory-to-memory with PFC (FG fetch only with FG PFC active)

10: Memory-to-memory with blending (FG and BG fetch with PFC and blending)

11: Register-to-memory (no FG nor BG, only output stage active)

Bits 15:14 Reserved, must be kept at reset value

Bit 13 **CEIE**: Configuration Error Interrupt Enable

This bit is set and cleared by software.

0: CE interrupt disable

1: CE interrupt enable

Bit 12 **CTCIE**: CLUT transfer complete interrupt enable

This bit is set and cleared by software.

0: CTC interrupt disable

1: CTC interrupt enable

Bit 11 **CAEIE**: CLUT access error interrupt enable

This bit is set and cleared by software.

0: CAE interrupt disable

1: CAE interrupt enable

Bit 10 **TWIE**: Transfer watermark interrupt enable

This bit is set and cleared by software.

0: TW interrupt disable

1: TW interrupt enable

Bit 9 **TCIE**: Transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disable

1: TC interrupt enable

Bit 8 **TEIE**: Transfer error interrupt enable

This bit is set and cleared by software.

0: TE interrupt disable

1: TE interrupt enable

Bits 7:3 Reserved, must be kept at reset value

Bit 2 **ABORT**: Abort

This bit can be used to abort the current transfer. This bit is set by software and is automatically reset by hardware when the START bit is reset.

0: No transfer abort requested

1: Transfer abort requested

Bit 1 **SUSP**: Suspend

This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when the START bit is reset.

0: Transfer not suspended

1: Transfer suspended

Bit 0 **START**: Start

This bit can be used to launch the DMA2D according to the parameters loaded in the various configuration registers. This bit is automatically reset by the following events:

- At the end of the transfer
- When the data transfer is aborted by the user application by setting the ABORT bit in DMA2D\_CR
- When a data transfer error occurs
- When the data transfer has not started due to a configuration error or another transfer operation already ongoing (automatic CLUT loading).

## 11.5.2 DMA2D Interrupt Status Register (DMA2D\_ISR)

Address offset: 0x0004

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |      |       |       |      |      |      |
|----------|----|----|----|----|----|----|----|----|----|------|-------|-------|------|------|------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21   | 20    | 19    | 18   | 17   | 16   |
| Reserved |    |    |    |    |    |    |    |    |    |      |       |       |      |      |      |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5    | 4     | 3     | 2    | 1    | 0    |
| Reserved |    |    |    |    |    |    |    |    |    | CEIF | CTCIF | CAEIF | TWIF | TCIF | TEIF |
|          |    |    |    |    |    |    |    |    |    | r    | r     | r     | r    | r    | r    |

Bits 31:6 Reserved, must be kept at reset value

Bit 5 **CEIF**: Configuration error interrupt flag

This bit is set when the START bit of DMA2D\_CR, DMA2DFGPFCCR or DMA2D\_BGPFCCR is set and a wrong configuration has been programmed.

Bit 4 **CTCIF**: CLUT transfer complete interrupt flag

This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3 **CAEIF**: CLUT access error interrupt flag

This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2 **TWIF**: Transfer watermark interrupt flag

This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1 **TCIF**: Transfer complete interrupt flag

This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0 **TEIF**: Transfer error interrupt flag

This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

### 11.5.3 DMA2D interrupt flag clear register (DMA2D\_IFCR)

Address offset: 0x0008

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |       |        |        |       |       |       |
|----------|----|----|----|----|----|----|----|----|----|-------|--------|--------|-------|-------|-------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21    | 20     | 19     | 18    | 17    | 16    |
| Reserved |    |    |    |    |    |    |    |    |    |       |        |        |       |       |       |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5     | 4      | 3      | 2     | 1     | 0     |
| Reserved |    |    |    |    |    |    |    |    |    | CCEIF | CCTCIF | CAECIF | CTWIF | CTCIF | CTEIF |
|          |    |    |    |    |    |    |    |    |    | rc_w1 | rc_w1  | rc_w1  | rc_w1 | rc_w1 | rc_w1 |

Bits 31:6 Reserved, must be kept at reset value

Bit 5 **CCEIF**: Clear configuration error interrupt flag

Programming this bit to 1 clears the CEIF flag in the DMA2D\_ISR register

Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag

Programming this bit to 1 clears the CTCIF flag in the DMA2D\_ISR register

Bit 3 **CAECIF**: Clear CLUT access error interrupt flag

Programming this bit to 1 clears the CAEIF flag in the DMA2D\_ISR register

Bit 2 **CTWIF**: Clear transfer watermark interrupt flag

Programming this bit to 1 clears the TWIF flag in the DMA2D\_ISR register

Bit 1 **CTCIF**: Clear transfer complete interrupt flag

Programming this bit to 1 clears the TCIF flag in the DMA2D\_ISR register

Bit 0 **CTEIF**: Clear Transfer error interrupt flag

Programming this bit to 1 clears the TEIF flag in the DMA2D\_ISR register

### 11.5.4 DMA2D foreground memory address register (DMA2D\_FGMAR)

Address offset: 0x000C

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **MA[31: 0]**: Memory address

Address of the data used for the foreground image. This register can only be written when data transfers are disabled. Once the data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

### 11.5.5 DMA2D foreground offset register (DMA2D\_FGOR)

Address offset: 0x0010

Reset value: 0x0000 0000

|          |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29       | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13       | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    | LO[13:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |
|          |    | rW       | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13: 0]**: Line offset

Line offset used for the foreground expressed in pixel. This value is used to generate the address. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once a data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

### 11.5.6 DMA2D background memory address register (DMA2D\_BGMR)

Address offset: 0x0014

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31: 0 **MA[31: 0]**: Memory address

Address of the data used for the background image. This register can only be written when data transfers are disabled. Once a data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

### 11.5.7 DMA2D background offset register (DMA2D\_BGOR)

Address offset: 0x0018

Reset value: 0x0000 0000

|          |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29       | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13       | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    | LO[13:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |
|          |    | rW       | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13: 0]**: Line offset

Line offset used for the background image (expressed in pixel). This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

### 11.5.8 DMA2D foreground PFC control register (DMA2D\_FGPFCCR)

Address offset: 0x001C

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |          |    |       |     |         |    |    |    |
|------------|----|----|----|----|----|----|----|----------|----|-------|-----|---------|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21    | 20  | 19      | 18 | 17 | 16 |
| ALPHA[7:0] |    |    |    |    |    |    |    | Reserved |    |       |     |         |    |    |    |
|            |    |    |    |    |    |    |    |          |    |       |     |         |    |    |    |
|            |    |    |    |    |    |    |    |          |    |       |     |         |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw |          |    |       |     |         |    |    |    |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5     | 4   | 3       | 2  | 1  | 0  |
| CS[7:0]    |    |    |    |    |    |    |    | Reserved |    | START | CCM | CM[3:0] |    |    |    |
|            |    |    |    |    |    |    |    |          |    | rs    | rw  | rw      | rw | rw | rw |
|            |    |    |    |    |    |    |    |          |    |       |     |         |    |    |    |
|            |    |    |    |    |    |    |    |          |    |       |     |         |    |    |    |

Bits 31:24 **ALPHA[7: 0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied by the original alpha value according to the alpha mode selected through the AM[1:0] bits.

These bits can only be written when data transfers are disabled. Once a transfer has started, they become read-only.

Bits 23:18 Reserved, must be kept at reset value

Bits 17:16 **AM[1: 0]**: Alpha mode

These bits select the alpha channel value to be used for the foreground image. They can only be written data the transfer are disabled. Once the transfer has started, they become read-only.

00: No modification of the foreground image alpha channel value

01: Replace original foreground image alpha channel value by ALPHA[7: 0]

10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value

other configurations are meaningless

Bits 15:8 **CS[7: 0]**: CLUT size

These bits define the size of the CLUT used for the foreground image. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value

Bit 5 **START**: Start

This bit can be set to start the automatic loading of the CLUT. It is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in DMA2D\_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer).

Bit 4 **CCM**: CLUT color mode

This bit defines the color format of the CLUT. It can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.

0: ARGB8888

1: RGB888

others: meaningless

Bits 3:0 **CM[3: 0]**: Color mode

These bits defines the color format of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

0000: ARGB8888

0001: RGB888

0010: RGB565

0011: ARGB1555

0100: ARGB4444

0101: L8

0110: AL44

0111: AL88

1000: L4

1001: A8

1010: A4

others: meaningless

### 11.5.9 DMA2D foreground color register (DMA2D\_FGCOLR)

Address offset: 0x0020

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23        | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved   |    |    |    |    |    |    |    | RED[7:0]  |    |    |    |    |    |    |    |
|            |    |    |    |    |    |    |    | rw        | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7         | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| GREEN[7:0] |    |    |    |    |    |    |    | BLUE[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw        | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 Reserved, must be kept at reset value

Bits 23:16 **RED[7: 0]**: Red Value

These bits defines the red value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 **GREEN[7: 0]**: Green Value

These bits defines the green value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.

Bits 7:0 **BLUE[7: 0]**: Blue Value

These bits defines the blue value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.

### 11.5.10 DMA2D background PFC control register (DMA2D\_BGPFCCR)

Address offset: 0x0024

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |          |       |     |         |    |    |         |    |
|------------|----|----|----|----|----|----|----|----------|-------|-----|---------|----|----|---------|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22    | 21  | 20      | 19 | 18 | 17      | 16 |
| ALPHA[7:0] |    |    |    |    |    |    |    | Reserved |       |     |         |    |    | AM[1:0] |    |
| rw         | rw | rw | rw | rw | rw | rw | rw |          |       |     |         |    |    | rw      | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6     | 5   | 4       | 3  | 2  | 1       | 0  |
| CS[7:0]    |    |    |    |    |    |    |    | Reserved | START | CCM | CM[3:0] |    |    |         |    |
| rw         | rw | rw | rw | rw | rw | rw | rw |          | rs    | rw  | rw      | rw | rw | rw      |    |

Bits 31:24 **ALPHA[7: 0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied with the original alpha value according to the alpha mode selected with bits AM[1: 0]. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:18 Reserved, must be kept at reset value

Bits 17:16 **AM[1: 0]**: Alpha mode

These bits define which alpha channel value to be used for the background image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

00: No modification of the foreground image alpha channel value

01: Replace original background image alpha channel value by ALPHA[7: 0]

10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value

others: meaningless

Bits 15:8 **CS[7: 0]**: CLUT size

These bits define the size of the CLUT used for the BG. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value

Bit 5 **START**: Start

This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:

- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in the DMA2D\_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic foreground CLUT transfer).

Bit 4 **CCM**: CLUT Color mode

These bits define the color format of the CLUT. This register can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.

0: ARGB8888

1: RGB888

others: meaningless

Bits 3:0 **CM[3:0]**: Color mode

These bits define the color format of the foreground image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

0000: ARGB8888

0001: RGB888

0010: RGB565

0011: ARGB1555

0100: ARGB4444

0101: L8

0110: AL44

0111: AL88

1000: L4

1001: A8

1010: A4

others: meaningless

### 11.5.11 DMA2D background color register (DMA2D\_BGCOLR)

Address offset: 0x0028

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23        | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved   |    |    |    |    |    |    |    | RED[7:0]  |    |    |    |    |    |    |    |
|            |    |    |    |    |    |    |    | rw        | rw | rw | rw | rw | rw | rw | rw |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7         | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| GREEN[7:0] |    |    |    |    |    |    |    | BLUE[7:0] |    |    |    |    |    |    |    |
| rw         | rw | rw | rw | rw | rw | rw | rw | rw        | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 Reserved, must be kept at reset value

Bits 23:16 **RED[7: 0]**: Red Value

These bits define the red value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 **GREEN[7: 0]**: Green Value

These bits define the green value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:0 **BLUE[7: 0]**: Blue Value

These bits define the blue value for the A4 or A8 mode of the background. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 11.5.12 DMA2D foreground CLUT memory address register (DMA2D\_FGCMAR)

Address offset: 0x002C

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31: 0 **MA[31: 0]**: Memory Address

Address of the data used for the CLUT address dedicated to the foreground image. This register can only be written when no transfer is ongoing. Once the CLUT transfer has started, this register is read-only.

If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.

### 11.5.13 DMA2D background CLUT memory address register (DMA2D\_BGCMAR)

Address offset: 0x0030

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31: 0 **MA[31: 0]**: Memory address

Address of the data used for the CLUT address dedicated to the background image.  
This register can only be written when no transfer is on going. Once the CLUT transfer has started, this register is read-only.  
If the background CLUT format is 32-bit, the address must be 32-bit aligned.

### 11.5.14 DMA2D output PFC control register (DMA2D\_OPFCCR)

Address offset: 0x0034

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |         |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|---------|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19      | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |         |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3       | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    | CM[2:0] |    |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    | rw      | rw | rw |    |

Bits 31: 3 Reserved, must be kept at reset value

Bits 2: 0 **CM[2: 0]**: Color mode

These bits define the color format of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

000: ARGB8888

001: RGB888

010: RGB565

011: ARGB1555

100: ARGB4444

others: meaningless

### 11.5.15 DMA2D output color register (DMA2D\_OCOLR)

Address offset: 0x0038

Reset value: 0x0000 0000

|            |          |    |    |            |    |            |    |            |           |    |           |           |    |    |    |
|------------|----------|----|----|------------|----|------------|----|------------|-----------|----|-----------|-----------|----|----|----|
| 31         | 30       | 29 | 28 | 27         | 26 | 25         | 24 | 23         | 22        | 21 | 20        | 19        | 18 | 17 | 16 |
| ALPHA[7:0] |          |    |    |            |    |            |    | RED[7:0]   |           |    |           |           |    |    |    |
| rw         | rw       | rw | rw | rw         | rw | rw         | rw | rw         | rw        | rw | rw        | rw        | rw | rw | rw |
| 15         | 14       | 13 | 12 | 11         | 10 | 9          | 8  | 7          | 6         | 5  | 4         | 3         | 2  | 1  | 0  |
| GREEN[7:0] |          |    |    |            |    |            |    | BLUE[7:0]  |           |    |           |           |    |    |    |
| RED[4:0]   |          |    |    | GREEN[5:0] |    |            |    |            | BLUE[4:0] |    |           |           |    |    |    |
| A          | RED[4:0] |    |    |            |    | GREEN[4:0] |    |            |           |    | BLUE[4:0] |           |    |    |    |
| ALPHA[3:0] |          |    |    | RED[3:0]   |    |            |    | GREEN[3:0] |           |    |           | BLUE[3:0] |    |    |    |
| rw         | rw       | rw | rw | rw         | rw | rw         | rw | rw         | rw        | rw | rw        | rw        | rw | rw | rw |

Bits 31:24 **ALPHA[7: 0]**: Alpha Channel Value

These bits define the alpha channel of the output color. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:16 **RED[7: 0]**: Red Value

These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 **GREEN[7: 0]**: Green Value

These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:0 **BLUE[7: 0]**: Blue Value

These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

11.5.16 DMA2D output memory address register (DMA2D\_OMAR)

Address offset: 0x003C

Reset value: 0x0000 0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31        | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| MA[31:16] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MA[15:0]  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31: 0 **MA[31: 0]**: Memory Address

Address of the data used for the output FIFO. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.  
The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.

### 11.5.17 DMA2D output offset register (DMA2D\_OOR)

Address offset: 0x0040

Reset value: 0x0000 0000

|          |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29       | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13       | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    | LO[13:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |
|          |    | rW       | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:14 Reserved, must be kept at reset value

Bits 13:0 **LO[13:0]**: Line Offset

Line offset used for the output (expressed in pixels). This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 11.5.18 DMA2D number of line register (DMA2D\_NLR)

Address offset: 0x0044

Reset value: 0x0000 0000

|          |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29       | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    | PL[13:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |
|          |    | rW       | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15       | 14 | 13       | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| NL[15:0] |    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW       | rW | rW       | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:30 Reserved, must be kept at reset value

Bits 29:16 **PL[13:0]**: Pixel per lines

Number of pixels per lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only. If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 **NL[15:0]**: Number of lines

Number of lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 11.5.19 DMA2D line watermark register (DMA2D\_LWR)

Address offset: 0x0048

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| LW[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW       | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 Reserved, must be kept at reset value

Bits 15:0 **LW[15:0]**: Line watermark

These bits allow to configure the line watermark for interrupt generation.

An interrupt is raised when the last pixel of the watermarked line has been transferred.

These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 11.5.20 DMA2D AHB master timer configuration register (DMA2D\_AMTCR)

Address offset: 0x004C

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DT[7:0]  |    |    |    |    |    |    |    | Reserved |    |    |    |    |    |    | EN |
| rW       | rW | rW | rW | rW | rW | rW | rW |          |    |    |    |    |    |    | rW |

Bits 31:16 Reserved

Bits 15:8 **DT[7: 0]**: Dead Time

Dead time value in the AHB clock cycle inserted between two consecutive accesses on the AHB master port. These bits represent the minimum guaranteed number of cycles between two consecutive AHB accesses.

Bits 7:1 Reserved

Bit 0 **EN**: Enable

Enables the dead time functionality.

## 11.5.21 DMA2D register map

The following table summarizes the DMA2D registers. Refer to [Section 2.3: Memory map](#) for the DMA2D register base address.

**Table 60. DMA2D register map and reset values**

| Offset | Register      | 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24       | 23 | 22 | 21 | 20 | 19 | 18 | 17         | 16         | 15       | 14       | 13       | 12         | 11         | 10        | 9          | 8         | 7         | 6         | 5       | 4        | 3      | 2       | 1     | 0     |       |       |

## 12 Interrupts and events

This Section applies to the whole STM32F4xx family, unless otherwise specified.

### 12.1 Nested vectored interrupt controller (NVIC)

#### 12.1.1 NVIC features

The nested vector interrupt controller NVIC includes the following features:

- **82 maskable interrupt channels** for STM32F405xx/07xx and STM32F415xx/17xx, and up to 91 maskable interrupt channels for STM32F42xxx and STM32F43xxx (not including the 16 interrupt lines of Cortex®-M4 with FPU)
- **16 programmable priority levels** (4 bits of interrupt priority are used)
- low-latency exception and interrupt handling
- power management control
- implementation of system control registers

The **NVIC and the processor core interface are closely coupled**, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts including the core exceptions are managed by the NVIC. For more information on exceptions and NVIC programming, refer to programming manual PM0214.

#### 12.1.2 SysTick calibration value register

The SysTick calibration value is fixed to 18750, which gives a reference time base of 1 ms with the SysTick clock set to 18.75 MHz (HCLK/8, with HCLK set to 150 MHz).

#### 12.1.3 Interrupt and exception vectors

See [Table 62](#) and [Table 62](#), for the vector table for the STM32F405xx/07xx and STM32F415xx/17xx and STM32F42xxx and STM32F43xxx devices.

### 12.2 External interrupt/event controller (EXTI)

The external interrupt/event controller **consists of up to 23 edge detectors for generating event/interrupt requests**. Each input line can be independently configured to select the type (interrupt or event) and the corresponding trigger event (rising or falling or both). Each line can also masked independently. A pending register maintains the status line of the interrupt requests.

The grey rows in the following tables describe the vectors without specific position.

Table 61. Vector table for STM32F405xx/07xx and STM32F415xx/17xx

| Position | Priority | Type of priority | Acronym       | Description                                                                              | Address                   |
|----------|----------|------------------|---------------|------------------------------------------------------------------------------------------|---------------------------|

### 12.2.1 EXTI main features

The main features of the EXTI controller are the following:

- independent trigger and mask on each interrupt/event line
- dedicated status bit for each interrupt line
- generation of up to 23 software event/interrupt requests
- detection of external signals with a pulse width lower than the APB2 clock period. Refer to the electrical characteristics section of the STM32F4xx datasheets for details on this parameter.

### 12.2.2 EXTI block diagram

Figure 41 shows the block diagram.

Figure 41. External interrupt/event controller block diagram

### 12.2.3 Wakeup event management

The STM32F4xx are able to handle external or internal events in order to wake up the core (WFE). The wakeup event can be generated either by:

- enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex®-M4 with FPU System Control register. When the MCU resumes from WFE, the peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
- or configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

To use an external line as a wakeup event, refer to [Section 12.2.4: Functional description](#).

### 12.2.4 Functional description

To generate the interrupt, the interrupt line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the interrupt request by writing a '1' to the corresponding bit in the interrupt mask register. When the selected edge occurs on the external interrupt line, an interrupt request is

generated. The pending bit corresponding to the interrupt line is also set. This request is reset by writing a '1' in the pending register.

To generate the event, the event line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the event request by writing a '1' to the corresponding bit in the event mask register. When the selected edge occurs on the event line, an event pulse is generated. The pending bit corresponding to the event line is not set.

An interrupt/event request can also be generated by software by writing a '1' in the software interrupt/event register.

### Hardware interrupt selection

To configure the 23 lines as interrupt sources, use the following procedure:

- Configure the mask bits of the 23 interrupt lines (EXTI\_IMR)
- Configure the Trigger selection bits of the interrupt lines (EXTI\_RTISR and EXTI\_FTISR)
- Configure the enable and mask bits that control the NVIC IRQ channel mapped to the external interrupt controller (EXTI) so that an interrupt coming from one of the 23 lines can be correctly acknowledged.

### Hardware event selection

To configure the 23 lines as event sources, use the following procedure:

- Configure the mask bits of the 23 event lines (EXTI\_EMR)
- Configure the Trigger selection bits of the event lines (EXTI\_RTISR and EXTI\_FTISR)

### Software interrupt/event selection

The 23 lines can be configured as software interrupt/event lines. The following is the procedure to generate a software interrupt.

- Configure the mask bits of the 23 interrupt/event lines (EXTI\_IMR, EXTI\_EMR)
- Set the required bit in the software interrupt register (EXTI\_SWIER)

### 12.2.5 External interrupt/event line mapping

Up to 140 GPIOs (STM32F405xx/07xx and STM32F415xx/17xx), 168 GPIOs (STM32F42xxx and STM32F43xxx) are connected to the 16 external interrupt/event lines in the following manner:

**Figure 42. External interrupt/event GPIO mapping (STM32F405xx/07xx and STM32F415xx/17xx)**

**Figure 43. External interrupt/event GPIO mapping (STM32F42xxx and STM32F43xxx)**

The seven other EXTI lines are connected as follows:

- EXTI line 16 is connected to the PVD output
- EXTI line 17 is connected to the RTC Alarm event
- EXTI line 18 is connected to the USB OTG FS Wakeup event
- EXTI line 19 is connected to the Ethernet Wakeup event
- EXTI line 20 is connected to the USB OTG HS (configured in FS) Wakeup event
- EXTI line 21 is connected to the RTC Tamper and TimeStamp events
- EXTI line 22 is connected to the RTC Wakeup event

## 12.3 EXTI registers

Refer to [Section 1.1: List of abbreviations for registers](#) for a list of abbreviations used in register descriptions.

### 12.3.1 Interrupt mask register (EXTI\_IMR)

Address offset: 0x00

Reset value: 0x0000 0000

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **MRx**: Event mask on line x

0: Event request from line x is masked

1: Event request from line x is not masked

### 12.3.3 Rising trigger selection register (EXTI\_RTSR)

Address offset: 0x08

Reset value: 0x0000 0000

|          |      |      |      |      |      |     |     |     |      |      |      |      |      |      |      |
|----------|------|------|------|------|------|-----|-----|-----|------|------|------|------|------|------|------|
| 31       | 30   | 29   | 28   | 27   | 26   | 25  | 24  | 23  | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Reserved |      |      |      |      |      |     |     |     | TR22 | TR21 | TR20 | TR19 | TR18 | TR17 | TR16 |
|          |      |      |      |      |      |     |     |     | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |
| 15       | 14   | 13   | 12   | 11   | 10   | 9   | 8   | 7   | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| TR15     | TR14 | TR13 | TR12 | TR11 | TR10 | TR9 | TR8 | TR7 | TR6  | TR5  | TR4  | TR3  | TR2  | TR1  | TR0  |
| r/w      | r/w  | r/w  | r/w  | r/w  | r/w  | r/w | r/w | r/w | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **TRx**: Rising trigger event configuration bit of line x

0: Rising trigger disabled (for Event and Interrupt) for input line

1: Rising trigger enabled (for Event and Interrupt) for input line

**Note:** *The external wakeup lines are edge triggered, no glitch must be generated on these lines. If a rising edge occurs on the external interrupt line while writing to the EXTI\_RTISR register, the pending bit is be set.*

*Rising and falling edge triggers can be set for the same interrupt line. In this configuration, both generate a trigger condition.*

### 12.3.4 Falling trigger selection register (EXTI\_FTSR)

Address offset: 0x0C

Reset value: 0x0000 0000

|          |      |      |      |      |      |     |     |     |      |      |      |      |      |      |      |
|----------|------|------|------|------|------|-----|-----|-----|------|------|------|------|------|------|------|
| 31       | 30   | 29   | 28   | 27   | 26   | 25  | 24  | 23  | 22   | 21   | 20   | 19   | 18   | 17   | 16   |
| Reserved |      |      |      |      |      |     |     |     | TR22 | TR21 | TR20 | TR19 | TR18 | TR17 | TR16 |
|          |      |      |      |      |      |     |     |     | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  | r/w  |
| 15       | 14   | 13   | 12   | 11   | 10   | 9   | 8   | 7   | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| TR15     | TR14 | TR13 | TR12 | TR11 | TR10 | TR9 | TR8 | TR7 | TR6  | TR5  | TR4  | TR3  | TR2  | TR1  | TR0  |

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **TRx**: Falling trigger event configuration bit of line x

0: Falling trigger disabled (for Event and Interrupt) for input line

1: Falling trigger enabled (for Event and Interrupt) for input line.

**Note:** *The external wakeup lines are edge triggered, no glitch must be generated on these lines. If a falling edge occurs on the external interrupt line while writing to the EXTI\_FTSR register, the pending bit is not set.*

*Rising and falling edge triggers can be set for the same interrupt line. In this configuration, both generate a trigger condition.*

### 12.3.5 Software interrupt event register (EXTI\_SWIER)

Address offset: 0x10

Reset value: 0x0000 0000

| 31          | 30          | 29          | 28          | 27          | 26          | 25         | 24         | 23         | 22          | 21          | 20          | 19          | 18          | 17          | 16          |
|-------------|-------------|-------------|-------------|-------------|-------------|------------|------------|------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| Reserved    |             |             |             |             |             |            |            |            | SWIER<br>22 | SWIER<br>21 | SWIER<br>20 | SWIER<br>19 | SWIER<br>18 | SWIER<br>17 | SWIER<br>16 |
|             |             |             |             |             |             |            |            |            | rw          | rw          | rw          | rw          | rw          | rw          | rw          |
| 15          | 14          | 13          | 12          | 11          | 10          | 9          | 8          | 7          | 6           | 5           | 4           | 3           | 2           | 1           | 0           |
| SWIER<br>15 | SWIER<br>14 | SWIER<br>13 | SWIER<br>12 | SWIER<br>11 | SWIER<br>10 | SWIER<br>9 | SWIER<br>8 | SWIER<br>7 | SWIER<br>6  | SWIER<br>5  | SWIER<br>4  | SWIER<br>3  | SWIER<br>2  | SWIER<br>1  | SWIER<br>0  |
| rw          | rw          | rw          | rw          | rw          | rw          | rw         | rw         | rw         | rw          | rw          | rw          | rw          | rw          | rw          | rw          |

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **SWIERx**: Software Interrupt on line x

If interrupt are enabled on line x in the EXTI\_IMR register, writing '1' to SWIERx bit when it is set at '0' sets the corresponding pending bit in the EXTI\_PR register, thus resulting in an interrupt request generation.

This bit is cleared by clearing the corresponding bit in EXTI\_PR (by writing a 1 to the bit).

### 12.3.6 Pending register (EXTI\_PR)

Address offset: 0x14

Reset value: undefined

| 31       | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 13 Analog-to-digital converter (ADC)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 13.1 ADC introduction

The 12-bit ADC is a successive approximation analog-to-digital converter. It has up to 19 multiplexed channels allowing it to measure signals from 16 external sources, two internal sources, and the  $V_{BAT}$  channel. The A/D conversion of the channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored into a left- or right-aligned 16-bit data register.

The analog watchdog feature allows the application to detect if the input voltage goes beyond the user-defined, higher or lower thresholds.

### 13.2 ADC main features

- 12-bit, 10-bit, 8-bit or 6-bit configurable resolution
- Interrupt generation at the end of conversion, end of injected conversion, and in case of analog watchdog or overrun events
- Single and continuous conversion modes
- Scan mode for automatic conversion of channel 0 to channel 'n'
- Data alignment with in-built data coherency
- Channel-wise programmable sampling time
- External trigger option with configurable polarity for both regular and injected conversions
- Discontinuous mode
- Dual/Triple mode (on devices with 2 ADCs or more)
- Configurable DMA data storage in Dual/Triple ADC mode
- Configurable delay between conversions in Dual/Triple interleaved mode
- ADC conversion type (refer to the datasheets)
- ADC supply requirements: 2.4 V to 3.6 V at full speed and down to 1.8 V at slower speed
- ADC input range:  $V_{REF-} \leq V_{IN} \leq V_{REF+}$
- DMA request generation during regular channel conversion

[Figure 44](#) shows the block diagram of the ADC.

*Note:*  $V_{REF-}$ , if available (depending on package), must be tied to  $V_{SSA}$ .

### 13.3 ADC functional description

Figure 44 shows a single ADC block diagram and Table 65 gives the ADC pin description.

Figure 44. Single ADC block diagram

Table 65. ADC pins

| Name          | Signal type                      | Remarks                                                                                                                                                                       |
|---------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $V_{REF+}$    | Input, analog reference positive | The higher/positive reference voltage for the ADC, $1.8\text{ V} \leq V_{REF+} \leq V_{DDA}$                                                                                  |
| $V_{DDA}$     | Input, analog supply             | Analog power supply equal to $V_{DD}$ and $2.4\text{ V} \leq V_{DDA} \leq V_{DD}$ (3.6 V) for full speed<br>$1.8\text{ V} \leq V_{DDA} \leq V_{DD}$ (3.6 V) for reduced speed |
| $V_{REF-}$    | Input, analog reference negative | The lower/negative reference voltage for the ADC, $V_{REF-} = V_{SSA}$                                                                                                        |
| $V_{SSA}$     | Input, analog supply ground      | Ground for analog power supply equal to $V_{SS}$                                                                                                                              |
| ADCx_IN[15:0] | Analog input signals             | 16 analog input channels                                                                                                                                                      |

### 13.3.1 ADC on-off control

The ADC is powered on by setting the ADON bit in the ADC\_CR2 register. When the ADON bit is set for the first time, it wakes up the ADC from the Power-down mode.

Conversion starts when either the SWSTART or the JSWSTART bit is set.

You can stop conversion and put the ADC in power down mode by clearing the ADON bit. In this mode the ADC consumes almost no power (only a few  $\mu\text{A}$ ).

### 13.3.2 ADC clock

The ADC features two clock schemes:

- Clock for the analog circuitry: ADCCLK, common to all ADCs  
This clock is generated from the APB2 clock divided by a programmable prescaler that allows the ADC to work at  $f_{PCLK2}/2$ ,  $/4$ ,  $/6$  or  $/8$ . Refer to the datasheets for the maximum value of ADCCLK.
- Clock for the digital interface (used for registers read/write access)  
This clock is equal to the APB2 clock. The digital interface clock can be enabled/disabled individually for each ADC through the RCC APB2 peripheral clock enable register (RCC\_APB2ENR).

### 13.3.3 Channel selection

There are 16 multiplexed channels. It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC\_IN3, ADC\_IN8, ADC\_IN2, ADC\_IN2, ADC\_IN0, ADC\_IN2, ADC\_IN2, ADC\_IN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC\_SQRx registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC\_SQR1 register.
- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC\_JSQR register.

The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC\_JSQR register.

If the ADC\_SQRx or ADC\_JSQR registers are modified during a conversion, the current conversion is reset and a new start pulse is sent to the ADC to convert the newly chosen group.

#### Temperature sensor, V<sub>REFINT</sub> and V<sub>BAT</sub> internal channels

- For the STM32F40x and STM32F41x devices, the temperature sensor is internally connected to channel ADC1\_IN16.  
The internal reference voltage VREFINT is connected to ADC1\_IN17.
- For the STM32F42x and STM32F43x devices, the temperature sensor is internally connected to ADC1\_IN18 channel which is shared with VBAT. Only one conversion, temperature sensor or VBAT, must be selected at a time. When the temperature sensor and VBAT conversion are set simultaneously, only the VBAT conversion is performed.  
The internal reference voltage VREFINT is connected to ADC1\_IN17.

The V<sub>BAT</sub> channel (connected to channel ADC1\_IN18) can also be converted as an injected or regular channel.

*Note: The temperature sensor, V<sub>REFINT</sub> and the V<sub>BAT</sub> channel are available only on the master ADC1 peripheral.*

### 13.3.4 Single conversion mode

In Single conversion mode the ADC does one conversion. This mode is started with the CONT bit at 0 by either:

- setting the SWSTART bit in the ADC\_CR2 register (for a regular channel only)
- setting the JSWSTART bit (for an injected channel)
- external trigger (for a regular or injected channel)

Once the conversion of the selected channel is complete:

- If a regular channel was converted:
  - The converted data are stored into the 16-bit ADC\_DR register
  - The EOC (end of conversion) flag is set
  - An interrupt is generated if the EOCIE bit is set
- If an injected channel was converted:
  - The converted data are stored into the 16-bit ADC\_JDR1 register
  - The JEOC (end of conversion injected) flag is set
  - An interrupt is generated if the JEOCIE bit is set

Then the ADC stops.

### 13.3.5 Continuous conversion mode

In continuous conversion mode, the ADC starts a new conversion as soon as it finishes one. This mode is started with the CONT bit at 1 either by external trigger or by setting the SWSTART bit in the ADC\_CR2 register (for regular channels only).

After each conversion:

- If a regular group of channels was converted:
  - The last converted data are stored into the 16-bit ADC\_DR register
  - The EOC (end of conversion) flag is set
  - An interrupt is generated if the EOCIE bit is set

**Note:** *Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to [Auto-injection](#) section).*

### 13.3.6 Timing diagram

As shown in [Figure 45](#), the ADC needs a stabilization time of  $t_{\text{STAB}}$  before it starts converting accurately. After the start of the ADC conversion and after 15 clock cycles, the EOC flag is set and the 16-bit ADC data register contains the result of the conversion.

**Figure 45. Timing diagram**

### 13.3.7 Analog watchdog

The AWD analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold. These thresholds are programmed in the 12 least significant bits of the ADC\_HTR and ADC\_LTR 16-bit registers. An interrupt can be enabled by using the AWDIE bit in the ADC\_CR1 register.

The threshold value is independent of the alignment selected by the ALIGN bit in the ADC\_CR2 register. The analog voltage is compared to the lower and higher thresholds before alignment.

[Table 66](#) shows how the ADC\_CR1 register should be configured to enable the analog watchdog on one or more channels.

Figure 46. Analog watchdog's guarded area

Table 66. Analog watchdog channel selection

| Channels guarded by the analog watchdog           | ADC_CR1 register control bits (x = don't care) |           |            |
|---------------------------------------------------|------------------------------------------------|-----------|------------|
|                                                   | AWDSGL bit                                     | AWDEN bit | JAWDEN bit |
| None                                              | x                                              | 0         | 0          |
| All injected channels                             | 0                                              | 0         | 1          |
| All regular channels                              | 0                                              | 1         | 0          |
| All regular and injected channels                 | 0                                              | 1         | 1          |
| Single <sup>(1)</sup> injected channel            | 1                                              | 0         | 1          |
| Single <sup>(1)</sup> regular channel             | 1                                              | 1         | 0          |
| Single <sup>(1)</sup> regular or injected channel | 1                                              | 1         | 1          |

1. Selected by the AWDCH[4:0] bits

### 13.3.8 Scan mode

This mode is used to scan a group of analog channels.

The Scan mode is selected by setting the SCAN bit in the ADC\_CR1 register. Once this bit has been set, the ADC scans all the channels selected in the ADC\_SQRx registers (for regular channels) or in the ADC\_JSQR register (for injected channels). A single conversion is performed for each channel of the group. After each end of conversion, the next channel in the group is converted automatically. If the CONT bit is set, regular channel conversion does not stop at the last selected channel in the group but continues again from the first selected channel.

If the DMA bit is set, the direct memory access (DMA) controller is used to transfer the data converted from the regular group of channels (stored in the ADC\_DR register) to SRAM after each regular channel conversion.

The EOC bit is set in the ADC\_SR register:

- At the end of each regular group sequence if the EOCS bit is cleared to 0
- At the end of each regular channel conversion if the EOCS bit is set to 1

The data converted from an injected channel are always stored into the ADC\_JDRx registers.

### 13.3.9 Injected channel management

#### Triggered injection

To use triggered injection, the JAUTO bit must be cleared in the ADC\_CR1 register.

1. Start the conversion of a group of regular channels either by external trigger or by setting the SWSTART bit in the ADC\_CR2 register.
  2. If an external injected trigger occurs or if the JSWSTART bit is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches to Scan-once mode.
  3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
- If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence.
- Figure 47 shows the corresponding timing diagram.*

**Note:** *When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 3 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.*

#### Auto-injection

If the JAUTO bit is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC\_SQRx and ADC\_JSQR registers.

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

**Note:** *It is not possible to use both the auto-injected and discontinuous modes simultaneously.*

**Figure 47. Injected conversion latency**

1. The maximum latency value can be found in the electrical characteristics of the STM32F40x and STM32F41x datasheets.

### 13.3.10 Discontinuous mode

#### Regular group

This mode is enabled by setting the DISCEN bit in the ADC\_CR1 register. It can be used to convert a short sequence of  $n$  conversions ( $n \leq 8$ ) that is part of the sequence of conversions selected in the ADC\_SQRx registers. The value of  $n$  is specified by writing to the DISCNUM[2:0] bits in the ADC\_CR1 register.

When an external trigger occurs, it starts the next  $n$  conversions selected in the ADC\_SQRx registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC\_SQR1 register.

Example:

- $n = 3$ , channels to be converted = 0, 1, 2, 3, 6, 7, 9, 10
- 1st trigger: sequence converted 0, 1, 2. An EOC event is generated at each conversion.
- 2nd trigger: sequence converted 3, 6, 7. An EOC event is generated at each conversion
- 3rd trigger: sequence converted 9, 10. An EOC event is generated at each conversion
- 4th trigger: sequence converted 0, 1, 2. An EOC event is generated at each conversion

*Note: When a regular group is converted in discontinuous mode, no rollover occurs.*

*When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 0, 1 and 2 in the 1st subgroup.*

#### Injected group

This mode is enabled by setting the JDISCEN bit in the ADC\_CR1 register. It can be used to convert the sequence selected in the ADC\_JSQR register, channel by channel, after an external trigger event.

When an external trigger occurs, it starts the next channel conversions selected in the ADC\_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC\_JSQR register.

Example:

- $n = 1$ , channels to be converted = 1, 2, 3
- 1st trigger: channel 1 converted
- 2nd trigger: channel 2 converted
- 3rd trigger: channel 3 converted and JEOP event generated
- 4th trigger: channel 1

*Note: When all injected channels are converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.*

*It is not possible to use both the auto-injected and discontinuous modes simultaneously.*

*Discontinuous mode must not be set for regular and injected groups at the same time.*

*Discontinuous mode must be enabled only for the conversion of one group.*

## 13.4 Data alignment

The ALIGN bit in the ADC\_CR2 register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in [Figure 48](#) and [Figure 49](#).

The converted data value from the injected group of channels is decreased by the user-defined offset written in the ADC\_JOFRx registers so the result can be a negative value. The SEXT bit represents the extended sign value.

For channels in a regular group, no offset is subtracted so only twelve bits are significant.

**Figure 48. Right alignment of 12-bit data**

**Figure 49. Left alignment of 12-bit data**

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in [Figure 50](#).

**Figure 50. Left alignment of 6-bit data**

### 13.5 Channel-wise programmable sampling time

The ADC samples the input voltage for a number of ADCCLK cycles that can be modified using the SMP[2:0] bits in the ADC\_SMPR1 and ADC\_SMPR2 registers. Each channel can be sampled with a different sampling time.

The total conversion time is calculated as follows:

$$T_{\text{conv}} = \text{Sampling time} + 12 \text{ cycles}$$

Example:

With ADCCLK = 30 MHz and sampling time = 3 cycles:

$$T_{\text{conv}} = 3 + 12 = 15 \text{ cycles} = 0.5 \mu\text{s with APB2 at 60 MHz}$$

### 13.6 Conversion on external trigger and trigger polarity

Conversion can be triggered by an external event (e.g. timer capture, EXTI line). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from “0b00”, then external events are able to trigger a conversion with the selected polarity. [Table 67](#) provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

**Table 67. Configuring the trigger polarity**

| Source                                         | EXTEN[1:0] / JEXTEN[1:0] |
|------------------------------------------------|--------------------------|
| Trigger detection disabled                     | 00                       |
| Detection on the rising edge                   | 01                       |
| Detection on the falling edge                  | 10                       |
| Detection on both the rising and falling edges | 11                       |

*Note:* The polarity of the external trigger can be changed on the fly.

The EXTSEL[3:0] and JEXTSEL[3:0] control bits are used to select which out of 16 possible events can trigger conversion for the regular and injected groups.

[Table 68](#) gives the possible external trigger for regular conversion.

Table 68. External trigger for regular channels

| Source          | Type                                | EXTSEL[3:0] |
|-----------------|-------------------------------------|-------------|
| TIM1_CH1 event  | Internal signal from on-chip timers | 0000        |
| TIM1_CH2 event  |                                     | 0001        |
| TIM1_CH3 event  |                                     | 0010        |
| TIM2_CH2 event  |                                     | 0011        |
| TIM2_CH3 event  |                                     | 0100        |
| TIM2_CH4 event  |                                     | 0101        |
| TIM2_TRGO event |                                     | 0110        |
| TIM3_CH1 event  |                                     | 0111        |
| TIM3_TRGO event |                                     | 1000        |
| TIM4_CH4 event  |                                     | 1001        |
| TIM5_CH1 event  |                                     | 1010        |
| TIM5_CH2 event  |                                     | 1011        |
| TIM5_CH3 event  |                                     | 1100        |
| TIM8_CH1 event  |                                     | 1101        |
| TIM8_TRGO event |                                     | 1110        |
| EXTI line11     | External pin                        | 1111        |

[Table 69](#) gives the possible external trigger for injected conversion.

Table 69. External trigger for injected channels

| Source          | Connection type                     | JEXTSEL[3:0] |
|-----------------|-------------------------------------|--------------|
| TIM1_CH4 event  | Internal signal from on-chip timers | 0000         |
| TIM1_TRGO event |                                     | 0001         |
| TIM2_CH1 event  |                                     | 0010         |
| TIM2_TRGO event |                                     | 0011         |
| TIM3_CH2 event  |                                     | 0100         |
| TIM3_CH4 event  |                                     | 0101         |
| TIM4_CH1 event  |                                     | 0110         |
| TIM4_CH2 event  |                                     | 0111         |
| TIM4_CH3 event  |                                     | 1000         |
| TIM4_TRGO event |                                     | 1001         |
| TIM5_CH4 event  |                                     | 1010         |
| TIM5_TRGO event |                                     | 1011         |
| TIM8_CH2 event  |                                     | 1100         |
| TIM8_CH3 event  |                                     | 1101         |
| TIM8_CH4 event  |                                     | 1110         |
| EXTI line15     | External pin                        | 1111         |

Software source trigger events can be generated by setting SWSTART (for regular conversion) or JSWSTART (for injected conversion) in ADC\_CR2.

A regular group conversion can be interrupted by an injected trigger.

**Note:** *The trigger selection can be changed on the fly. However, when the selection changes, there is a time frame of 1 APB clock cycle during which the trigger detection is disabled. This is to avoid spurious detection during transitions.*

## 13.7 Fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution. The RES bits are used to select the number of bits available in the data register. The minimum conversion time for each resolution is then as follows:

- 12 bits:  $3 + 12 = 15$  ADCCLK cycles
- 10 bits:  $3 + 10 = 13$  ADCCLK cycles
- 8 bits:  $3 + 8 = 11$  ADCCLK cycles
- 6 bits:  $3 + 6 = 9$  ADCCLK cycles

## 13.8 Data management

### 13.8.1 Using the DMA

Since converted regular channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one regular channel. This avoids the loss of the data already stored in the ADC\_DR register.

When the DMA mode is enabled (DMA bit set to 1 in the ADC\_CR2 register), after each conversion of a regular channel, a DMA request is generated. This allows the transfer of the converted data from the ADC\_DR register to the destination location selected by the software.

Despite this, if data are lost (overflow), the OVR bit in the ADC\_SR register is set and an interrupt is generated (if the OVRIE enable bit is set). DMA transfers are then disabled and DMA requests are no longer accepted. In this case, if a DMA request is made, the regular conversion in progress is aborted and further regular triggers are ignored. It is then necessary to clear the OVR flag and the DMAEN bit in the used DMA stream, and to re-initialize both the DMA and the ADC to have the wanted converted channel data transferred to the right memory location. Only then can the conversion be resumed and the data transfer, enabled again. Injected channel conversions are not impacted by overflow errors.

When OVR = 1 in DMA mode, the DMA requests are blocked after the last valid data have been transferred, which means that all the data transferred to the RAM can be considered as valid.

At the end of the last DMA transfer (number of transfers configured in the DMA controller's DMA\_SxNDTR register):

- No new DMA request is issued to the DMA controller if the DDS bit is cleared to 0 in the ADC\_CR2 register (this avoids generating an overflow error). However the DMA bit is not cleared by hardware. It must be written to 0, then to 1 to start a new transfer.
- Requests can continue to be generated if the DDS bit is set to 1. This allows configuring the DMA in double-buffer circular mode.

To recover the ADC from OVR state when the DMA is used, follow the steps below:

1. Reinitialize the DMA (adjust destination address and NDTR counter)
2. Clear the ADC OVR bit in ADC\_SR register
3. Trigger the ADC to start the conversion.

### 13.8.2 Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the EOCS bit must be set in the ADC\_CR2 register for the EOC status bit to be set at the end of each conversion, and not only at the end of the sequence. When EOCS = 1, overflow detection is automatically enabled. Thus, each time a conversion is complete, EOC is set and the ADC\_DR register can be read. The overflow management is the same as when the DMA is used.

To recover the ADC from OVR state when the EOCS is set, follow the steps below:

1. Clear the ADC OVR bit in ADC\_SR register
2. Trigger the ADC to start the conversion.

### 13.8.3 Conversions without DMA and without overrun detection

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). For that, the DMA must be disabled (DMA = 0) and the EOC bit must be set at the end of a sequence only (EOCS = 0). In this configuration, overrun detection is disabled.

## 13.9 Multi ADC mode

In devices with two ADCs or more, the Dual (with two ADCs) and Triple (with three ADCs) ADC modes can be used (see [Figure 51](#)).

In multi ADC mode, the start of conversion is triggered alternately or simultaneously by the ADC1 master to the ADC2 and ADC3 slaves, depending on the mode selected by the MULTI[4:0] bits in the ADC\_CCR register.

*Note:* In multi ADC mode, when configuring conversion trigger by an external event, the application must set trigger by the master only and disable trigger by slaves to prevent spurious triggers that would start unwanted slave conversions.

The four possible modes below are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use the previous modes combined in the following ways:

- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode

*Note:* In multi ADC mode, the converted data can be read on the multi-mode data register (ADC\_CDR). The status bits can be read in the multi-mode status register (ADC\_CSR).

Figure 51. Multi ADC block diagram<sup>(1)</sup>

1. Although external triggers are present on ADC2 and ADC3 they are not shown in this diagram.
2. In the Dual ADC mode, the ADC3 slave part is not present.
3. In Triple ADC mode, the ADC common data register (ADC\_CDR) contains the ADC1, ADC2 and ADC3's regular converted data. All 32 register bits are used according to a selected storage order.  
In Dual ADC mode, the ADC common data register (ADC\_CDR) contains both the ADC1 and ADC2's regular converted data. All 32 register bits are used.

- DMA requests in Multi ADC mode:
 

In Multi ADC mode the DMA may be configured to transfer converted data in three different modes. In all cases, the DMA streams to use are those connected to the ADC:

  - **DMA mode 1:** On each DMA request (one data item is available), a half-word representing an ADC-converted data item is transferred.
 

In Triple ADC mode, ADC1 data are transferred on the first request, ADC2 data are transferred on the second request and ADC3 data are transferred on the third request; the sequence is repeated. So the DMA first transfers ADC1 data followed by ADC2 data followed by ADC3 data and so on.

DMA mode 1 is used in regular simultaneous triple mode only.

**Example:**

Regular simultaneous triple mode: 3 consecutive DMA requests are generated (one for each converted data item)

1st request: ADC\_CDR[31:0] = ADC1\_DR[15:0]  
 2nd request: ADC\_CDR[31:0] = ADC2\_DR[15:0]  
 3rd request: ADC\_CDR[31:0] = ADC3\_DR[15:0]  
 4th request: ADC\_CDR[31:0] = ADC1\_DR[15:0]
  - **DMA mode 2:** On each DMA request (two data items are available) two half-words representing two ADC-converted data items are transferred as a word.
 

In Dual ADC mode, both ADC2 and ADC1 data are transferred on the first request (ADC2 data take the upper half-word and ADC1 data take the lower half-word) and so on.

In Triple ADC mode, three DMA requests are generated. On the first request, both ADC2 and ADC1 data are transferred (ADC2 data take the upper half-word and ADC1 data take the lower half-word). On the second request, both ADC1 and ADC3 data are transferred (ADC1 data take the upper half-word and ADC3 data take the lower half-word). On the third request, both ADC3 and ADC2 data are transferred (ADC3 data take the upper half-word and ADC2 data take the lower half-word) and so on.

DMA mode 2 is used in interleaved mode and in regular simultaneous mode (for Dual ADC mode only).

**Example:**

    - a) Interleaved dual mode: a DMA request is generated each time 2 data items are available:
 

1st request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]  
 2nd request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]
    - b) Interleaved triple mode: a DMA request is generated each time 2 data items are available
 

1st request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]  
 2nd request: ADC\_CDR[31:0] = ADC1\_DR[15:0] | ADC3\_DR[15:0]  
 3rd request: ADC\_CDR[31:0] = ADC3\_DR[15:0] | ADC2\_DR[15:0]  
 4th request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]
  - **DMA mode 3:** This mode is similar to the DMA mode 2. The only differences are that the on each DMA request (two data items are available) two bytes

representing two ADC converted data items are transferred as a half-word. The data transfer order is similar to that of the DMA mode 2.

DMA mode 3 is used in interleaved mode in 6-bit and 8-bit resolutions (dual and triple mode).

**Example:**

- a) Interleaved dual mode: a DMA request is generated each time 2 data items are available  
 1st request: `ADC_CDR[15:0] = ADC2_DR[7:0] | ADC1_DR[7:0]`  
 2nd request: `ADC_CDR[15:0] = ADC2_DR[7:0] | ADC1_DR[7:0]`
- b) Interleaved triple mode: a DMA request is generated each time 2 data items are available  
 1st request: `ADC_CDR[15:0] = ADC2_DR[7:0] | ADC1_DR[7:0]`  
 2nd request: `ADC_CDR[15:0] = ADC1_DR[7:0] | ADC3_DR[7:0]`  
 3rd request: `ADC_CDR[15:0] = ADC3_DR[7:0] | ADC2_DR[7:0]`  
 4th request: `ADC_CDR[15:0] = ADC2_DR[7:0] | ADC1_DR[7:0]`

**Overflow detection:** If an overflow is detected on one of the concerned ADCs (ADC1 and ADC2 in dual and triple modes, ADC3 in triple mode only), the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid. It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

### 13.9.1 Injected simultaneous mode

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of ADC1 (selected by the JEXTSEL[3:0] bits in the ADC1\_CR2 register). A simultaneous trigger is provided to ADC2 and ADC3.

*Note: Do not convert the same channel on the two/three ADCs (no overlapping sampling times for the two/three ADCs when converting the same channel).*

*In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences (Dual ADC mode) /3 sequences (Triple ADC mode). Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.*

*Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.*

### Dual ADC mode

At the end of conversion event on ADC1 or ADC2:

- The converted data are stored into the ADC\_JDRx registers of each ADC interface.
- A JEOC interrupt is generated (if enabled on one of the two ADC interfaces) when the ADC1/ADC2's injected channels have all been converted.

**Figure 52. Injected simultaneous mode on 4 channels: dual ADC mode**

### Triple ADC mode

At the end of conversion event on ADC1, ADC2 or ADC3:

- The converted data are stored into the ADC\_JDRx registers of each ADC interface.
- A JEOC interrupt is generated (if enabled on one of the three ADC interfaces) when the ADC1/ADC2/ADC3's injected channels have all been converted.

**Figure 53. Injected simultaneous mode on 4 channels: triple ADC mode**

## 13.9.2 Regular simultaneous mode

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of ADC1 (selected by the EXTSEL[3:0] bits in the ADC1\_CR2 register). A simultaneous trigger is provided to ADC2 and ADC3.

**Note:** *Do not convert the same channel on the two/three ADCs (no overlapping sampling times for the two/three ADCs when converting the same channel).*

*In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences (Dual ADC mode) / 3 sequences (Triple ADC mode). Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.*

*Injected conversions must be disabled.*

### Dual ADC mode

At the end of conversion event on ADC1 or ADC2:

- A 32-bit DMA transfer request is generated (if DMA[1:0] bits in the ADC\_CCR register are equal to 0b10). This request transfers the ADC2 converted data stored in the upper half-word of the ADC\_CDR 32-bit register to the SRAM and then the ADC1 converted data stored in the lower half-word of ADC\_CDR to the SRAM.
- An EOC interrupt is generated (if enabled on one of the two ADC interfaces) when the ADC1/ADC2's regular channels have all been converted.

**Figure 54. Regular simultaneous mode on 16 channels: dual ADC mode**

### Triple ADC mode

At the end of conversion event on ADC1, ADC2 or ADC3:

- Three 32-bit DMA transfer requests are generated (if DMA[1:0] bits in the ADC\_CCR register are equal to 0b01). Three transfers then take place from the ADC\_CDR 32-bit register to SRAM: first the ADC1 converted data, then the ADC2 converted data and finally the ADC3 converted data. The process is repeated for each new three conversions.
- An EOC interrupt is generated (if enabled on one of the three ADC interfaces) when the ADC1/ADC2/ADC3's regular channels are have all been converted.

**Figure 55. Regular simultaneous mode on 16 channels: triple ADC mode**

### 13.9.3 Interleaved mode

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of ADC1.

#### Dual ADC mode

After an external trigger occurs:

- ADC1 starts immediately
- ADC2 starts after a delay of several-ADC clock cycles

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADC\_CCR register. However, an ADC cannot start a conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time). In this case, the delay becomes the sampling time + 2 ADC clock cycles. For instance, if DELAY = 5 clock cycles and the sampling takes 15 clock cycles on both ADCs, then 17 clock cycles will separate conversions on ADC1 and ADC2).

If the CONT bit is set on both ADC1 and ADC2, the selected regular channels of both ADCs are continuously converted.

*Note: If the conversion sequence is interrupted (for instance when DMA end of transfer occurs), the multi-ADC sequencer must be reset by configuring it in independent mode first (bits DUAL[4:0] = 00000) before reprogramming the interleaved mode.*

After an EOC interrupt is generated by ADC2 (if enabled through the EOCIE bit) a 32-bit DMA transfer request is generated (if the DMA[1:0] bits in ADC\_CCR are equal to 0b10). This request first transfers the ADC2 converted data stored in the upper half-word of the ADC\_CDR 32-bit register into SRAM, then the ADC1 converted data stored in the register's lower half-word into SRAM.

**Figure 56. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode**

#### Triple ADC mode

After an external trigger occurs:

- ADC1 starts immediately and
- ADC2 starts after a delay of several ADC clock cycles
- ADC3 starts after a delay of several ADC clock cycles referred to the ADC2 conversion

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADC\_CCR register. However, an ADC cannot start a conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at

a given time). In this case, the delay becomes the sampling time + 2 ADC clock cycles. For instance, if DELAY = 5 clock cycles and the sampling takes 15 clock cycles on the three ADCs, then 17 clock cycles will separate the conversions on ADC1, ADC2 and ADC3).

If the CONT bit is set on ADC1, ADC2 and ADC3, the selected regular channels of all ADCs are continuously converted.

**Note:** *If the conversion sequence is interrupted (for instance when DMA end of transfer occurs), the multi-ADC sequencer must be reset by configuring it in independent mode first (bits DUAL[4:0] = 00000) before reprogramming the interleaved mode.*

In this mode a DMA request is generated each time 2 data items are available, (if the DMA[1:0] bits in the ADC\_CCR register are equal to 0b10). The request first transfers the first converted data stored in the lower half-word of the ADC\_CDR 32-bit register to SRAM, then it transfers the second converted data stored in ADC\_CDR's upper half-word to SRAM. The sequence is the following:

- 1st request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0]
- 2nd request: ADC\_CDR[31:0] = ADC1\_DR[15:0] | ADC3\_DR[15:0]
- 3rd request: ADC\_CDR[31:0] = ADC3\_DR[15:0] | ADC2\_DR[15:0]
- 4th request: ADC\_CDR[31:0] = ADC2\_DR[15:0] | ADC1\_DR[15:0], ...

**Figure 57. Interleaved mode on 1 channel in continuous conversion mode: triple ADC mode**

### 13.9.4 Alternate trigger mode

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of ADC1.

**Note:** *Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the*

ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

If the conversion sequence is interrupted (for instance when DMA end of transfer occurs), the multi-ADC sequencer must be reset by configuring it in independent mode first (bits  $DUAL[4:0] = 00000$ ) before reprogramming the interleaved mode.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.

### Dual ADC mode

- When the 1st trigger occurs, all injected ADC1 channels in the group are converted
- When the 2nd trigger occurs, all injected ADC2 channels in the group are converted
- and so on

A JEOC interrupt, if enabled, is generated after all injected ADC1 channels in the group have been converted.

A JEOC interrupt, if enabled, is generated after all injected ADC2 channels in the group have been converted.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected ADC1 channels in the group.

**Figure 58. Alternate trigger: injected group of each ADC**

If the injected discontinuous mode is enabled for both ADC1 and ADC2:

- When the 1st trigger occurs, the first injected ADC1 channel is converted.
- When the 2nd trigger occurs, the first injected ADC2 channel are converted
- and so on

A JEOC interrupt, if enabled, is generated after all injected ADC1 channels in the group have been converted.

A JEOC interrupt, if enabled, is generated after all injected ADC2 channels in the group have been converted.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 59. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode****Triple ADC mode**

- When the 1st trigger occurs, all injected ADC1 channels in the group are converted.
- When the 2nd trigger occurs, all injected ADC2 channels in the group are converted.
- When the 3rd trigger occurs, all injected ADC3 channels in the group are converted.
- and so on

A JEOC interrupt, if enabled, is generated after all injected ADC1 channels in the group have been converted.

A JEOC interrupt, if enabled, is generated after all injected ADC2 channels in the group have been converted.

A JEOC interrupt, if enabled, is generated after all injected ADC3 channels in the group have been converted.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected ADC1 channels in the group.

**Figure 60. Alternate trigger: injected group of each ADC****13.9.5 Combined regular/injected simultaneous mode**

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

**Note:** *In combined regular/injected simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences (Dual ADC mode) / 3 sequences (Triple ADC mode). Otherwise, the*

ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

### 13.9.6 Combined regular simultaneous + alternate trigger mode

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. [Figure 61](#) shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

**Note:** *In combined regular simultaneous + alternate trigger mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences (Dual ADC mode) / 3 sequences (Triple ADC mode). Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.*

*If the conversion sequence is interrupted (for instance when DMA end of transfer occurs), the multi-ADC sequencer must be reset by configuring it in independent mode first (bits DUAL[4:0] = 00000) before reprogramming the interleaved mode.*

**Figure 61. Alternate + regular simultaneous**

If a trigger occurs during an injected conversion that has interrupted a regular conversion, it is ignored. [Figure 62](#) shows the behavior in this case (2nd trigger is ignored).

Figure 62. Case of trigger occurring during injected conversion

### 13.10 Temperature sensor

The temperature sensor can be used to measure the junction temperature ( $T_J$ ) of the device.

- On STM32F40x and STM32F41x devices, the temperature sensor is internally connected to ADC1\_IN16 channel which is used to convert the sensor output voltage to a digital value.
- On STM32F42x and STM32F43x devices, the temperature sensor is internally connected to the same input channel, ADC1\_IN18, as VBAT: ADC1\_IN18 is used to convert the sensor output voltage or VBAT into a digital value. Only one conversion, temperature sensor or VBAT, must be selected at a time. When the temperature sensor and the VBAT conversion are set simultaneously, only the VBAT conversion is performed.

Figure 63 shows the block diagram of the temperature sensor.

When not in use, the sensor can be put in power down mode.

**Note:** The *TSVREFE* bit must be set to enable the conversion of both internal channels: the ADC1\_IN16 or ADC1\_IN18 (temperature sensor) and the ADC1\_IN17 (VREFINT).

#### Main features

- Supported temperature range:  $-40$  to  $125$  °C
- Precision:  $\pm 1.5$  °C

**Figure 63. Temperature sensor and V<sub>REFINT</sub> channel block diagram**

1. V<sub>SENSE</sub> is input to ADC1\_IN16 for the STM23F40x and STM32F41x devices and to ADC1\_IN18 for the STM32F42x and STM32F43x devices.

### Reading the temperature

To use the sensor:

3. Select ADC1\_IN16 or ADC1\_IN18 input channel.
4. Select a sampling time greater than the minimum sampling time specified in the datasheet.
5. Set the TSVREFE bit in the ADC\_CCR register to wake up the temperature sensor from power down mode
6. Start the ADC conversion by setting the SWSTART bit (or by external trigger)
7. Read the resulting V<sub>SENSE</sub> data in the ADC data register
8. Calculate the temperature using the following formula:  

$$\text{Temperature (in } ^\circ\text{C)} = \{(V_{\text{SENSE}} - V_{25}) / \text{Avg\_Slope}\} + 25$$

Where:

  - V<sub>25</sub> = V<sub>SENSE</sub> value for 25° C
  - Avg\_Slope = average slope of the temperature vs. V<sub>SENSE</sub> curve (given in mV/°C or μV/°C)

Refer to the datasheet's electrical characteristics section for the actual values of V<sub>25</sub> and Avg\_Slope.

**Note:** *The sensor has a startup time after waking from power down mode before it can output V<sub>SENSE</sub> at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADON and TSVREFE bits should be set at the same time.*

The temperature sensor output voltage changes linearly with temperature. The offset of this linear function depends on each chip due to process variation (up to 45 °C from one chip to another).

The internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. If accurate temperature reading is required, an external temperature sensor should be used.

### 13.11 Battery charge monitoring

The VBATE bit in the ADC\_CCR register is used to switch to the battery voltage. As the  $V_{BAT}$  voltage could be higher than  $V_{DDA}$ , to ensure the correct operation of the ADC, the  $V_{BAT}$  pin is internally connected to a bridge divider.

When the VBATE is set, the bridge is automatically enabled to connect:

- $V_{BAT}/2$  to the ADC1\_IN18 input channel, on STM32F40xx and STM32F41xx devices
- $V_{BAT}/4$  to the ADC1\_IN18 input channel, on STM32F42xx and STM32F43xx devices

*Note:* On STM32F42xx and STM32F43xx devices, VBAT and temperature sensor are connected to the same ADC internal channel (ADC1\_IN18). Only one conversion, either temperature sensor or VBAT, must be selected at a time. When both conversion are enabled simultaneously, only the VBAT conversion is performed.

### 13.12 ADC interrupts

An interrupt can be produced on the end of conversion for regular and injected groups, when the analog watchdog status bit is set and when the overrun status bit is set. Separate interrupt enable bits are available for flexibility.

Two other flags are present in the ADC\_SR register, but there is no interrupt associated with them:

- JSTRT (Start of conversion for channels of an injected group)
- STRT (Start of conversion for channels of a regular group)

**Table 70. ADC interrupts**

| Interrupt event                        | Event flag | Enable control bit |
|----------------------------------------|------------|--------------------|
| End of conversion of a regular group   | EOC        | EOCIE              |
| End of conversion of an injected group | JEOC       | JEOCIE             |
| Analog watchdog status bit is set      | AWD        | AWDIE              |
| Overrun                                | OVR        | OVRIE              |

## 13.13 ADC registers

Refer to [Section 1.1: List of abbreviations for registers](#) for registers for a list of abbreviations used in register descriptions.

The peripheral registers must be written at word level (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

### 13.13.1 ADC status register (ADC\_SR)

Address offset: 0x00

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |       |       |       |       |       |       |
|----------|----|----|----|----|----|----|----|----|----|-------|-------|-------|-------|-------|-------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21    | 20    | 19    | 18    | 17    | 16    |
| Reserved |    |    |    |    |    |    |    |    |    |       |       |       |       |       |       |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5     | 4     | 3     | 2     | 1     | 0     |
| Reserved |    |    |    |    |    |    |    |    |    | OVR   | STRT  | JSTRT | JEOC  | EOC   | AWD   |
|          |    |    |    |    |    |    |    |    |    | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 |

Bits 31:6 Reserved, must be kept at reset value.

**Bit 5 OVR:** Overrun

This bit is set by hardware when data are lost (either in single mode or in dual/triple mode). It is cleared by software. Overrun detection is enabled only when DMA = 1 or EOCS = 1.

0: No overrun occurred  
1: Overrun has occurred

**Bit 4 STRT:** Regular channel start flag

This bit is set by hardware when regular channel conversion starts. It is cleared by software.

0: No regular channel conversion started  
1: Regular channel conversion has started

**Bit 3 JSTRT:** Injected channel start flag

This bit is set by hardware when injected group conversion starts. It is cleared by software.

0: No injected group conversion started  
1: Injected group conversion has started

**Bit 2 JEOC:** Injected channel end of conversion

This bit is set by hardware at the end of the conversion of all injected channels in the group. It is cleared by software.

0: Conversion is not complete  
1: Conversion complete

**Bit 1 EOC:** Regular channel end of conversion

This bit is set by hardware at the end of the conversion of a regular group of channels. It is cleared by software or by reading the ADC\_DR register.

0: Conversion not complete (EOCS=0), or sequence of conversions not complete (EOCS=1)  
1: Conversion complete (EOCS=0), or sequence of conversions complete (EOCS=1)

**Bit 0 AWD:** Analog watchdog flag

This bit is set by hardware when the converted voltage crosses the values programmed in the ADC\_LTR and ADC\_HTR registers. It is cleared by software.

0: No analog watchdog event occurred  
1: Analog watchdog event occurred

### 13.13.2 ADC control register 1 (ADC\_CR1)

Address offset: 0x04

Reset value: 0x0000 0000

|              |    |    |         |        |       |        |      |        |        |          |            |    |    |    |    |
|--------------|----|----|---------|--------|-------|--------|------|--------|--------|----------|------------|----|----|----|----|
| 31           | 30 | 29 | 28      | 27     | 26    | 25     | 24   | 23     | 22     | 21       | 20         | 19 | 18 | 17 | 16 |
| Reserved     |    |    |         |        | OVRIE | RES    |      | AWDEN  | JAWDEN | Reserved |            |    |    |    |    |
|              |    |    |         |        | rw    | rw     | rw   | rw     | rw     |          |            |    |    |    |    |
| 15           | 14 | 13 | 12      | 11     | 10    | 9      | 8    | 7      | 6      | 5        | 4          | 3  | 2  | 1  | 0  |
| DISCNUM[2:0] |    |    | JDISCEN | DISCEN | JAUTO | AWDSGL | SCAN | JEOCIE | AWDIE  | EOCIE    | AWDCH[4:0] |    |    |    |    |
| rw           | rw | rw | rw      | rw     | rw    | rw     | rw   | rw     | rw     | rw       | rw         | rw | rw | rw | rw |

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Bits 25:24 **RES[1:0]**: Resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit (15 ADCCLK cycles)

01: 10-bit (13 ADCCLK cycles)

10: 8-bit (11 ADCCLK cycles)

11: 6-bit (9 ADCCLK cycles)

Bit 23 **AWDEN**: Analog watchdog enable on regular channels

This bit is set and cleared by software.

0: Analog watchdog disabled on regular channels

1: Analog watchdog enabled on regular channels

Bit 22 **JAWDEN**: Analog watchdog enable on injected channels

This bit is set and cleared by software.

0: Analog watchdog disabled on injected channels

1: Analog watchdog enabled on injected channels

Bits 21:16 Reserved, must be kept at reset value.

Bits 15:13 **DISCNUM[2:0]**: Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Bit 12 **JDISCEN**: Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

- Bit 11 **DISCEN**: Discontinuous mode on regular channels  
 This bit is set and cleared by software to enable/disable Discontinuous mode on regular channels.  
 0: Discontinuous mode on regular channels disabled  
 1: Discontinuous mode on regular channels enabled
- Bit 10 **JAUTO**: Automatic injected group conversion  
 This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.  
 0: Automatic injected group conversion disabled  
 1: Automatic injected group conversion enabled
- Bit 9 **AWDSGL**: Enable the watchdog on a single channel in scan mode  
 This bit is set and cleared by software to enable/disable the analog watchdog on the channel identified by the AWDCH[4:0] bits.  
 0: Analog watchdog enabled on all channels  
 1: Analog watchdog enabled on a single channel
- Bit 8 **SCAN**: Scan mode  
 This bit is set and cleared by software to enable/disable the Scan mode. In Scan mode, the inputs selected through the ADC\_SQRx or ADC\_JSQRx registers are converted.  
 0: Scan mode disabled  
 1: Scan mode enabled  
*Note: An EOC interrupt is generated if the EOCIE bit is set:*  
 – At the end of each regular group sequence if the EOCS bit is cleared to 0  
 – At the end of each regular channel conversion if the EOCS bit is set to 1  
*Note: A JEOP interrupt is generated only on the end of conversion of the last channel if the JEOPIE bit is set.*
- Bit 7 **JEOPIE**: Interrupt enable for injected channels  
 This bit is set and cleared by software to enable/disable the end of conversion interrupt for injected channels.  
 0: JEOP interrupt disabled  
 1: JEOP interrupt enabled. An interrupt is generated when the JEOP bit is set.
- Bit 6 **AWDIE**: Analog watchdog interrupt enable  
 This bit is set and cleared by software to enable/disable the analog watchdog interrupt.  
 0: Analog watchdog interrupt disabled  
 1: Analog watchdog interrupt enabled
- Bit 5 **EOCIE**: Interrupt enable for EOC  
 This bit is set and cleared by software to enable/disable the end of conversion interrupt.  
 0: EOC interrupt disabled  
 1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
- Bits 4:0 **AWDCH[4:0]**: Analog watchdog channel select bits  
 These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.  
*Note:* 00000: ADC analog input Channel0  
 00001: ADC analog input Channel1  
 ...  
 01111: ADC analog input Channel15  
 10000: ADC analog input Channel16  
 10001: ADC analog input Channel17  
 10010: ADC analog input Channel18  
 Other values reserved

### 13.13.3 ADC control register 2 (ADC\_CR2)

Address offset: 0x08

Reset value: 0x0000 0000

| 31       | 30          | 29    | 28 | 27          | 26   | 25  | 24  | 23       | 22           | 21     | 20 | 19           | 18 | 17   | 16   |
|----------|-------------|-------|----|-------------|------|-----|-----|----------|--------------|--------|----|--------------|----|------|------|

| reserved |             |       |    | ALIGN       | EOCS | DDS | DMA | Reserved |              |        |    |              |    | CONT | ADON |
|          |             |       |    | rw          | rw   | rw  | rw  |          |              |        |    |              |    | rw   | rw   |

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SWSTART**: Start conversion of regular channels

This bit is set by software to start conversion and cleared by hardware as soon as the conversion starts.

0: Reset state

1: Starts conversion of regular channels

*Note: This bit can be set only when ADON = 1 otherwise no conversion is launched.*

Bits 29:28 **EXTEN**: External trigger enable for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Trigger detection disabled

01: Trigger detection on the rising edge

10: Trigger detection on the falling edge

11: Trigger detection on both the rising and falling edges

Bits 27:24 **EXTSEL[3:0]**: External event select for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

0000: Timer 1 CC1 event

0001: Timer 1 CC2 event

0010: Timer 1 CC3 event

0011: Timer 2 CC2 event

0100: Timer 2 CC3 event

0101: Timer 2 CC4 event

0110: Timer 2 TRGO event

0111: Timer 3 CC1 event

1000: Timer 3 TRGO event

1001: Timer 4 CC4 event

1010: Timer 5 CC1 event

1011: Timer 5 CC2 event

1100: Timer 5 CC3 event

1101: Timer 8 CC1 event

1110: Timer 8 TRGO event

1111: EXTI line11

Bit 23 Reserved, must be kept at reset value.

Bit 22 **JSWSTART**: Start conversion of injected channels

This bit is set by software and cleared by hardware as soon as the conversion starts.

0: Reset state

1: Starts conversion of injected channels

*Note: This bit can be set only when ADON = 1 otherwise no conversion is launched.*

Bits 21:20 **JEXTEN**: External trigger enable for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Trigger detection disabled

01: Trigger detection on the rising edge

10: Trigger detection on the falling edge

11: Trigger detection on both the rising and falling edges

Bits 19:16 **JEXTSEL[3:0]**: External event select for injected group

These bits select the external event used to trigger the start of conversion of an injected group.

0000: Timer 1 CC4 event

0001: Timer 1 TRGO event

0010: Timer 2 CC1 event

0011: Timer 2 TRGO event

0100: Timer 3 CC2 event

0101: Timer 3 CC4 event

0110: Timer 4 CC1 event

0111: Timer 4 CC2 event

1000: Timer 4 CC3 event

1001: Timer 4 TRGO event

1010: Timer 5 CC4 event

1011: Timer 5 TRGO event

1100: Timer 8 CC2 event

1101: Timer 8 CC3 event

1110: Timer 8 CC4 event

1111: EXTI line15

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **ALIGN**: Data alignment

This bit is set and cleared by software. Refer to [Figure 48](#) and [Figure 49](#).

0: Right alignment

1: Left alignment

Bit 10 **EOCS**: End of conversion selection

This bit is set and cleared by software.

0: The EOC bit is set at the end of each sequence of regular conversions. Overrun detection is enabled only if DMA=1.

1: The EOC bit is set at the end of each regular conversion. Overrun detection is enabled.

Bit 9 **DDS**: DMA disable selection (for single ADC mode)

This bit is set and cleared by software.

0: No new DMA request is issued after the last transfer (as configured in the DMA controller)

1: DMA requests are issued as long as data are converted and DMA=1

Bit 8 **DMA**: Direct memory access mode (for single ADC mode)

This bit is set and cleared by software. Refer to the DMA controller chapter for more details.

0: DMA mode disabled

1: DMA mode enabled

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CONT**: Continuous conversion

This bit is set and cleared by software. If it is set, conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Bit 0 **ADON**: A/D Converter ON / OFF

This bit is set and cleared by software.

Note: 0: Disable ADC conversion and go to power down mode

1: Enable ADC

### 13.13.4 ADC sample time register 1 (ADC\_SMPR1)

Address offset: 0x0C

Reset value: 0x0000 0000

|          |            |    |    |            |            |    |            |            |    |            |            |    |            |            |    |
|----------|------------|----|----|------------|------------|----|------------|------------|----|------------|------------|----|------------|------------|----|

Bits 31: 27 Reserved, must be kept at reset value.

Bits 26:0 **SMPx[2:0]**: Channel x sampling time selection

These bits are written by software to select the sampling time individually for each channel.

During sampling cycles, the channel selection bits must remain unchanged.

Note: 000: 3 cycles

001: 15 cycles

010: 28 cycles

011: 56 cycles

100: 84 cycles

101: 112 cycles

110: 144 cycles

111: 480 cycles

### 13.13.5 ADC sample time register 2 (ADC\_SMPR2)

Address offset: 0x10

Reset value: 0x0000 0000

|          |           |           |    |           |           |    |           |           |    |           |           |    |           |           |    |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]**: Channel x sampling time selection

These bits are written by software to select the sampling time individually for each channel.  
During sample cycles, the channel selection bits must remain unchanged.

Note: 000: 3 cycles  
001: 15 cycles  
010: 28 cycles  
011: 56 cycles  
100: 84 cycles  
101: 112 cycles  
110: 144 cycles  
111: 480 cycles

### 13.13.6 ADC injected channel data offset register x (ADC\_JOFRx) (x=1..4)

Address offset: 0x14-0x20

Reset value: 0x0000 0000

|          |    |    |    |                |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----------------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27             | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |                |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11             | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | JOFFSETx[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **JOFFSETx[11:0]**: Data offset for injected channel x

These bits are written by software to define the offset to be subtracted from the raw converted data when converting injected channels. The conversion result can be read from in the ADC\_JDRx registers.

### 13.13.7 ADC watchdog higher threshold register (ADC\_HTR)

Address offset: 0x24

Reset value: 0x0000 0FFF

|          |    |    |    |          |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27       | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |          |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11       | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | HT[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw       | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **HT[11:0]**: Analog watchdog higher threshold

These bits are written by software to define the higher threshold for the analog watchdog.

**Note:** *The software can write to these registers when an ADC conversion is ongoing. The programmed value will be effective when the next conversion is complete. Writing to this register is performed with a write delay that can create uncertainty on the effective time at which the new value is programmed.*

### 13.13.8 ADC watchdog lower threshold register (ADC\_LTR)

Address offset: 0x28

Reset value: 0x0000 0000

|          |    |    |    |          |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27       | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |          |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11       | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | LT[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw       | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **LT[11:0]**: Analog watchdog lower threshold

These bits are written by software to define the lower threshold for the analog watchdog.

**Note:** *The software can write to these registers when an ADC conversion is ongoing. The programmed value will be effective when the next conversion is complete. Writing to this register is performed with a write delay that can create uncertainty on the effective time at which the new value is programmed.*

### 13.13.9 ADC regular sequence register 1 (ADC\_SQR1)

Address offset: 0x2C

Reset value: 0x0000 0000

|          |           |    |    |    |    |           |    |        |    |    |           |           |    |    |    |
|----------|-----------|----|----|----|----|-----------|----|--------|----|----|-----------|-----------|----|----|----|
| 31       | 30        | 29 | 28 | 27 | 26 | 25        | 24 | 23     | 22 | 21 | 20        | 19        | 18 | 17 | 16 |
| Reserved |           |    |    |    |    |           |    | L[3:0] |    |    |           | SQ16[4:1] |    |    |    |
|          |           |    |    |    |    |           |    | rw     | rw | rw | rw        | rw        | rw | rw | rw |
| 15       | 14        | 13 | 12 | 11 | 10 | 9         | 8  | 7      | 6  | 5  | 4         | 3         | 2  | 1  | 0  |
| SQ16_0   | SQ15[4:0] |    |    |    |    | SQ14[4:0] |    |        |    |    | SQ13[4:0] |           |    |    |    |
| rw       | rw        | rw | rw | rw | rw | rw        | rw |        |    |    | rw        | rw        | rw | rw | rw |

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **L[3:0]**: Regular channel sequence length

These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion

0001: 2 conversions

...

1111: 16 conversions

Bits 19:15 **SQ16[4:0]**: 16th conversion in regular sequence

These bits are written by software with the channel number (0..18) assigned as the 16th in the conversion sequence.

Bits 14:10 **SQ15[4:0]**: 15th conversion in regular sequence

Bits 9:5 **SQ14[4:0]**: 14th conversion in regular sequence

Bits 4:0 **SQ13[4:0]**: 13th conversion in regular sequence

### 13.13.10 ADC regular sequence register 2 (ADC\_SQR2)

Address offset: 0x30

Reset value: 0x0000 0000

|          |          |           |    |    |    |          |           |    |    |    |          |           |    |    |    |
|----------|----------|-----------|----|----|----|----------|-----------|----|----|----|----------|-----------|----|----|----|
| 31       | 30       | 29        | 28 | 27 | 26 | 25       | 24        | 23 | 22 | 21 | 20       | 19        | 18 | 17 | 16 |
| Reserved |          | SQ12[4:0] |    |    |    |          | SQ11[4:0] |    |    |    |          | SQ10[4:1] |    |    |    |
|          |          | rw        | rw | rw | rw | rw       | rw        | rw | rw | rw | rw       | rw        | rw | rw | rw |
| 15       | 14       | 13        | 12 | 11 | 10 | 9        | 8         | 7  | 6  | 5  | 4        | 3         | 2  | 1  | 0  |
| SQ10_0   | SQ9[4:0] |           |    |    |    | SQ8[4:0] |           |    |    |    | SQ7[4:0] |           |    |    |    |
| rw       | rw       | rw        | rw | rw | rw | rw       | rw        | rw | rw | rw | rw       | rw        | rw | rw | rw |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:26 **SQ12[4:0]**: 12th conversion in regular sequence

These bits are written by software with the channel number (0..18) assigned as the 12th in the sequence to be converted.

Bits 24:20 **SQ11[4:0]**: 11th conversion in regular sequence

Bits 19:15 **SQ10[4:0]**: 10th conversion in regular sequence

Bits 14:10 **SQ9[4:0]**: 9th conversion in regular sequence

Bits 9:5 **SQ8[4:0]**: 8th conversion in regular sequence

Bits 4:0 **SQ7[4:0]**: 7th conversion in regular sequence

### 13.13.11 ADC regular sequence register 3 (ADC\_SQR3)

Address offset: 0x34

Reset value: 0x0000 0000

|          |          |          |    |    |    |          |          |    |    |    |          |          |    |    |    |
|----------|----------|----------|----|----|----|----------|----------|----|----|----|----------|----------|----|----|----|
| 31       | 30       | 29       | 28 | 27 | 26 | 25       | 24       | 23 | 22 | 21 | 20       | 19       | 18 | 17 | 16 |
| Reserved |          | SQ6[4:0] |    |    |    |          | SQ5[4:0] |    |    |    |          | SQ4[4:1] |    |    |    |
|          |          | rw       | rw | rw | rw | rw       | rw       | rw | rw | rw | rw       | rw       | rw | rw | rw |
| 15       | 14       | 13       | 12 | 11 | 10 | 9        | 8        | 7  | 6  | 5  | 4        | 3        | 2  | 1  | 0  |
| SQ4_0    | SQ3[4:0] |          |    |    |    | SQ2[4:0] |          |    |    |    | SQ1[4:0] |          |    |    |    |
| rw       | rw       | rw       | rw | rw | rw | rw       | rw       | rw | rw | rw | rw       | rw       | rw | rw | rw |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:25 **SQ6[4:0]**: 6th conversion in regular sequence

These bits are written by software with the channel number (0..18) assigned as the 6th in the sequence to be converted.

Bits 24:20 **SQ5[4:0]**: 5th conversion in regular sequence

Bits 19:15 **SQ4[4:0]**: 4th conversion in regular sequence

Bits 14:10 **SQ3[4:0]**: 3rd conversion in regular sequence

Bits 9:5 **SQ2[4:0]**: 2nd conversion in regular sequence

Bits 4:0 **SQ1[4:0]**: 1st conversion in regular sequence

### 13.13.12 ADC injected sequence register (ADC\_JSQR)

Address offset: 0x38

Reset value: 0x0000 0000

|          |    |           |    |    |    |           |    |    |    |           |    |           |    |    |    |
|----------|----|-----------|----|----|----|-----------|----|----|----|-----------|----|-----------|----|----|----|
| 31       | 30 | 29        | 28 | 27 | 26 | 25        | 24 | 23 | 22 | 21        | 20 | 19        | 18 | 17 | 16 |
| Reserved |    |           |    |    |    |           |    |    |    | JL[1:0]   |    | JSQ4[4:1] |    |    |    |
|          |    |           |    |    |    |           |    |    |    | rw        | rw | rw        | rw | rw | rw |
| 15       | 14 | 13        | 12 | 11 | 10 | 9         | 8  | 7  | 6  | 5         | 4  | 3         | 2  | 1  | 0  |
| JSQ4[0]  |    | JSQ3[4:0] |    |    |    | JSQ2[4:0] |    |    |    | JSQ1[4:0] |    |           |    |    |    |
| rw       | rw | rw        | rw | rw | rw | rw        | rw | rw | rw | rw        | rw | rw        | rw | rw | rw |

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **JL[1:0]**: Injected sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Bits 19:15 **JSQ4[4:0]**: 4th conversion in injected sequence (when JL[1:0]=3, see note below)

These bits are written by software with the channel number (0..18) assigned as the 4th in the sequence to be converted.

Bits 14:10 **JSQ3[4:0]**: 3rd conversion in injected sequence (when JL[1:0]=3, see note below)

Bits 9:5 **JSQ2[4:0]**: 2nd conversion in injected sequence (when JL[1:0]=3, see note below)

Bits 4:0 **JSQ1[4:0]**: 1st conversion in injected sequence (when JL[1:0]=3, see note below)

**Note:** When JL[1:0]=3 (4 injected conversions in the sequencer), the ADC converts the channels in the following order: JSQ1[4:0], JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0].

When JL=2 (3 injected conversions in the sequencer), the ADC converts the channels in the following order: JSQ2[4:0], JSQ3[4:0], and JSQ4[4:0].

When JL=1 (2 injected conversions in the sequencer), the ADC converts the channels in starting from JSQ3[4:0], and then JSQ4[4:0].

When JL=0 (1 injected conversion in the sequencer), the ADC converts only JSQ4[4:0] channel.

### 13.13.13 ADC injected data register x (ADC\_JDRx) (x= 1..4)

Address offset: 0x3C - 0x48

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| JDATA[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **JDATA[15:0]**: Injected data

These bits are read-only. They contain the conversion result from injected channel x. The data are left- or right-aligned as shown in [Figure 48](#) and [Figure 49](#).

### 13.13.14 ADC regular data register (ADC\_DR)

Address offset: 0x4C

Reset value: 0x0000 0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r          | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DATA[15:0]**: Regular data

These bits are read-only. They contain the conversion result from the regular channels. The data are left- or right-aligned as shown in [Figure 48](#) and [Figure 49](#).

### 13.13.15 ADC Common status register (ADC\_CSR)

Address offset: 0x00 (this offset address is relative to ADC1 base address + 0x300)

Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing it to 0 in the corresponding ADC\_SR register.

|          |    |      |       |            |       |      |      |          |    |      |       |        |        |      |      |

|          |    | ADC2 |       |            |       |      |      |          |    | ADC1 |       |        |        |      |      |
|          |    | r    | r     | r          | r     | r    | r    |          |    | r    | r     | r      | r      | r    | r    |

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OVR3**: Overrun flag of ADC3

This bit is a copy of the OVR bit in the ADC3\_SR register.

Bit 20 **STRT3**: Regular channel Start flag of ADC3

This bit is a copy of the STRT bit in the ADC3\_SR register.

Bit 19 **JSTRT3**: Injected channel Start flag of ADC3

This bit is a copy of the JSTRT bit in the ADC3\_SR register.

Bit 18 **JEOC3**: Injected channel end of conversion of ADC3

This bit is a copy of the JEOC bit in the ADC3\_SR register.

Bit 17 **EOC3**: End of conversion of ADC3

This bit is a copy of the EOC bit in the ADC3\_SR register.

Bit 16 **AWD3**: Analog watchdog flag of ADC3

This bit is a copy of the AWD bit in the ADC3\_SR register.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OVR2**: Overrun flag of ADC2

This bit is a copy of the OVR bit in the ADC2\_SR register.

Bit 12 **STRT2**: Regular channel Start flag of ADC2

This bit is a copy of the STRT bit in the ADC2\_SR register.

Bit 11 **JSTRT2**: Injected channel Start flag of ADC2

This bit is a copy of the JSTRT bit in the ADC2\_SR register.

Bit 10 **JEOC2**: Injected channel end of conversion of ADC2

This bit is a copy of the JEOC bit in the ADC2\_SR register.

Bit 9 **EOC2**: End of conversion of ADC2

This bit is a copy of the EOC bit in the ADC2\_SR register.

Bit 8 **AWD2**: Analog watchdog flag of ADC2

This bit is a copy of the AWD bit in the ADC2\_SR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **OVR1**: Overrun flag of ADC1

This bit is a copy of the OVR bit in the ADC1\_SR register.

Bit 4 **STRT1**: Regular channel Start flag of ADC1

This bit is a copy of the STRT bit in the ADC1\_SR register.

Bit 3 **JSTRT1**: Injected channel Start flag of ADC1

This bit is a copy of the JSTRT bit in the ADC1\_SR register.

Bit 2 **JEOC1**: Injected channel end of conversion of ADC1

This bit is a copy of the JEOC bit in the ADC1\_SR register.

Bit 1 **EOC1**: End of conversion of ADC1

This bit is a copy of the EOC bit in the ADC1\_SR register.

Bit 0 **AWD1**: Analog watchdog flag of ADC1

This bit is a copy of the AWD bit in the ADC1\_SR register.

### 13.13.16 ADC common control register (ADC\_CCR)

Address offset: 0x04 (this offset address is relative to ADC1 base address + 0x300)

Reset value: 0x0000 0000

|          |    |     |      |            |    |    |    |          |       |          |            |    |    |        |    |
|----------|----|-----|------|------------|----|----|----|----------|-------|----------|------------|----|----|--------|----|
| 31       | 30 | 29  | 28   | 27         | 26 | 25 | 24 | 23       | 22    | 21       | 20         | 19 | 18 | 17     | 16 |
| Reserved |    |     |      |            |    |    |    | TSVREFE  | VBATE | Reserved |            |    |    | ADCPRE |    |
|          |    |     |      |            |    |    |    | rw       | rw    |          |            |    |    | rw     | rw |
| 15       | 14 | 13  | 12   | 11         | 10 | 9  | 8  | 7        | 6     | 5        | 4          | 3  | 2  | 1      | 0  |
| DMA[1:0] |    | DDS | Res. | DELAY[3:0] |    |    |    | Reserved |       |          | MULTI[4:0] |    |    |        |    |
| rw       | rw | rw  |      | rw         | rw | rw | rw |          |       |          | rw         | rw | rw | rw     | rw |

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TSVREFE**: Temperature sensor and  $V_{REFINT}$  enable

This bit is set and cleared by software to enable/disable the temperature sensor and the  $V_{REFINT}$  channel.

0: Temperature sensor and  $V_{REFINT}$  channel disabled

1: Temperature sensor and  $V_{REFINT}$  channel enabled

*Note: On STM32F42x and STM32F43x devices, VBATE must be disabled when TSVREFE is set. If both bits are set, only the VBAT conversion is performed.*

Bit 22 **VBATE**:  $V_{BAT}$  enable

This bit is set and cleared by software to enable/disable the  $V_{BAT}$  channel.

0:  $V_{BAT}$  channel disabled

1:  $V_{BAT}$  channel enabled

Bits 21:18 Reserved, must be kept at reset value.

Bits 17:16 **ADCPRE**: ADC prescaler

Set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

Note: 00: PCLK2 divided by 2  
01: PCLK2 divided by 4  
10: PCLK2 divided by 6  
11: PCLK2 divided by 8

Bits 15:14 **DMA**: Direct memory access mode for multi ADC mode

This bit-field is set and cleared by software. Refer to the DMA controller section for more details.

00: DMA mode disabled  
01: DMA mode 1 enabled (2 / 3 half-words one by one - 1 then 2 then 3)  
10: DMA mode 2 enabled (2 / 3 half-words by pairs - 2&1 then 1&3 then 3&2)  
11: DMA mode 3 enabled (2 / 3 bytes by pairs - 2&1 then 1&3 then 3&2)

Bit 13 **DDS**: DMA disable selection (for multi-ADC mode)

This bit is set and cleared by software.

0: No new DMA request is issued after the last transfer (as configured in the DMA controller). DMA bits are not cleared by hardware, however they must have been cleared and set to the wanted mode by software before new DMA requests can be generated.

1: DMA requests are issued as long as data are converted and DMA = 01, 10 or 11.

Bit 12 Reserved, must be kept at reset value.

Bit 11:8 **DELAY**: Delay between 2 sampling phases

Set and cleared by software. These bits are used in dual or triple interleaved modes.

0000:  $5 * T_{ADCCLK}$

0001:  $6 * T_{ADCCLK}$

0010:  $7 * T_{ADCCLK}$

...

1111:  $20 * T_{ADCCLK}$

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **MULTI[4:0]**: Multi ADC mode selection

These bits are written by software to select the operating mode.

- All the ADCs independent:  
00000: Independent mode
- 00001 to 01001: Dual mode, ADC1 and ADC2 working together, ADC3 is independent  
00001: Combined regular simultaneous + injected simultaneous mode  
00010: Combined regular simultaneous + alternate trigger mode  
00011: Reserved  
00101: Injected simultaneous mode only  
00110: Regular simultaneous mode only  
00111: interleaved mode only  
01001: Alternate trigger mode only
- 10001 to 11001: Triple mode: ADC1, 2 and 3 working together  
10001: Combined regular simultaneous + injected simultaneous mode  
10010: Combined regular simultaneous + alternate trigger mode  
10011: Reserved  
10101: Injected simultaneous mode only  
10110: Regular simultaneous mode only  
10111: interleaved mode only  
11001: Alternate trigger mode only

All other combinations are reserved and must not be programmed

*Note: In multi mode, a change of channel configuration generates an abort that can cause a loss of synchronization. It is recommended to disable the multi ADC mode before any configuration change.*

### 13.13.17 ADC common regular data register for dual and triple modes (ADC\_CDR)

Address offset: 0x08 (this offset address is relative to ADC1 base address + 0x300)

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATA2[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATA1[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16 **DATA2[15:0]**: 2nd data item of a pair of regular conversions

- In dual mode, these bits contain the regular data of ADC2. Refer to [Dual ADC mode](#).
- In triple mode, these bits contain alternatively the regular data of ADC2, ADC1 and ADC3. Refer to [Triple ADC mode](#).

Bits 15:0 **DATA1[15:0]**: 1st data item of a pair of regular conversions

- In dual mode, these bits contain the regular data of ADC1. Refer to [Dual ADC mode](#).
- In triple mode, these bits contain alternatively the regular data of ADC1, ADC3 and ADC2. Refer to [Triple ADC mode](#).

### 13.13.18 ADC register map

The following table summarizes the ADC registers.

**Table 71. ADC global register map**

| Offset        | Register         |
|---------------|------------------|
| 0x000 - 0x04C | ADC1             |
| 0x050 - 0x0FC | Reserved         |
| 0x100 - 0x14C | ADC2             |
| 0x118 - 0x1FC | Reserved         |
| 0x200 - 0x24C | ADC3             |
| 0x250 - 0x2FC | Reserved         |
| 0x300 - 0x308 | Common registers |

Table 72. ADC register map and reset values for each ADC

| Offset | Register    | 31                      | 30                                  | 29         | 28           | 27    | 26       | 25          | 24       | 23                                  | 22            | 21                                    | 20 | 19             | 18 | 17                 | 16     | 15     | 14    | 13      | 12   | 11       | 10    | 9     | 8          | 7    | 6    | 5     | 4    | 3   | 2   | 1 | 0 |   |   |   |   |   |   |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 14 Digital-to-analog converter (DAC)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 14.1 DAC introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC has two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin,  $V_{REF+}$  (shared with ADC) is available for better resolution.

### 14.2 DAC main features

- Two DAC converters: one output channel each
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave generation
- Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel
- DMA underrun error detection
- External triggers for conversion
- Input voltage reference,  $V_{REF+}$

[Figure 64](#) shows the block diagram of a DAC channel and [Table 74](#) gives the pin description.

Figure 64. DAC channel block diagram

Table 74. DAC pins

| Name              | Signal type                      | Remarks                                                                                                    |
|-------------------|----------------------------------|------------------------------------------------------------------------------------------------------------|
| V <sub>REF+</sub> | Input, analog reference positive | The higher/positive reference voltage for the DAC, $1.8\text{ V} \leq V_{\text{REF+}} \leq V_{\text{DDA}}$ |
| V <sub>DDA</sub>  | Input, analog supply             | Analog power supply                                                                                        |
| V <sub>SSA</sub>  | Input, analog supply ground      | Ground for analog power supply                                                                             |
| DAC_OUTx          | Analog output signal             | DAC channelx analog output                                                                                 |

**Note:** Once the DAC channelx is enabled, the corresponding GPIO pin (PA4 or PA5) is automatically connected to the analog converter output (DAC\_OUTx). In order to avoid parasitic consumption, the PA4 or PA5 pin should first be configured to analog (AIN).

## 14.3 DAC functional description

### 14.3.1 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC\_CR register. The DAC channel is then enabled after a startup time  $t_{WAKEUP}$ .

*Note: The ENx bit enables the analog DAC Channelx macrocell only. The DAC Channelx digital interface is enabled even if the ENx bit is reset.*

### 14.3.2 DAC output buffer enable

The DAC integrates two output buffers that can be used to reduce the output impedance, and to drive external loads directly without having to add an external operational amplifier. Each DAC channel output buffer can be enabled and disabled using the corresponding BOFFx bit in the DAC\_CR register.

### 14.3.3 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channelx, there are three possibilities:
  - 8-bit right alignment: the software has to load data into the DAC\_DHR8Rx [7:0] bits (stored into the DHRx[11:4] bits)
  - 12-bit left alignment: the software has to load data into the DAC\_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
  - 12-bit right alignment: the software has to load data into the DAC\_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC\_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

Figure 65. Data registers in single DAC channel mode

- Dual DAC channels, there are three possibilities:
  - 8-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC\_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
  - 12-bit left alignment: data for DAC channel1 to be loaded into the DAC\_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
  - 12-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12LD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC\_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

Figure 66. Data registers in dual DAC channel mode

### 14.3.4 DAC conversion

The DAC\_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC\_DHRx register (write to DAC\_DHR8Rx, DAC\_DHR12Lx, DAC\_DHR12Rx, DAC\_DHR8RD, DAC\_DHR12LD or DAC\_DHR12LD).

Data stored in the DAC\_DHRx register are automatically transferred to the DAC\_DORx register after one APB1 clock cycle, if no hardware trigger is selected (TENx bit in DAC\_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC\_CR register is set) and a trigger occurs, the transfer is performed three APB1 clock cycles later.

When DAC\_DORx is loaded with the DAC\_DHRx contents, the analog output voltage becomes available after a time  $t_{\text{SETTLING}}$  that depends on the power supply voltage and the analog output load.

**Figure 67. Timing diagram for conversion with trigger disabled TEN = 0**

### 14.3.5 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and  $V_{\text{REF+}}$ .

The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DACoutput} = V_{\text{REF}} \times \frac{\text{DOR}}{4096}$$

### 14.3.6 DAC trigger selection

If the TENx control bit is set, conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[2:0] control bits determine which out of 8 possible events will trigger conversion as shown in [Table 75](#).

**Table 75. External triggers**

| Source             | Type                                | TSEL[2:0] |
|--------------------|-------------------------------------|-----------|
| Timer 6 TRGO event | Internal signal from on-chip timers | 000       |
| Timer 8 TRGO event |                                     | 001       |
| Timer 7 TRGO event |                                     | 010       |
| Timer 5 TRGO event |                                     | 011       |
| Timer 2 TRGO event |                                     | 100       |
| Timer 4 TRGO event |                                     | 101       |
| EXTI line9         | External pin                        | 110       |
| SWTRIG             | Software control bit                | 111       |

Each time a DAC interface detects a rising edge on the selected timer TRGO output, or on the selected external interrupt line 9, the last data stored into the DAC\_DHRx register are transferred into the DAC\_DORx register. The DAC\_DORx register is updated three APB1 cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC\_DORx register has been loaded with the DAC\_DHRx register contents.

*Note: TSELx[2:0] bit cannot be changed when the ENx bit is set.*

*When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DORx register takes only one APB1 clock cycle.*

### 14.3.7 DMA request

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

A DAC DMA request is generated when an external trigger (but not a software trigger) occurs while the DMAENx bit is set. The value of the DAC\_DHRx register is then transferred into the DAC\_DORx register.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, the user should set only the corresponding DMAENx bit. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

#### DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgement for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC\_SR register is set, reporting the error condition. DMA data transfers are then disabled and no further DMA request is treated. The DAC channelx continues to convert old data.

The software should clear the DMAUDRx flag by writing “1”, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software should modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC\_CR register is enabled.

### 14.3.8 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to “01”. The preloaded value in LFSR is 0xAAA. This register is updated three APB1 clock cycles after each trigger event, following a specific calculation algorithm.

Figure 68. DAC LFSR register calculation algorithm

The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC\_CR register, is added up to the DAC\_DHRx contents without overflow and this value is then stored into the DAC\_DORx register.

If LFSR is 0x0000, a '1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Figure 69. DAC conversion (SW trigger enabled) with LFSR wave generation

**Note:** The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC\_CR register.

### 14.3.9 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to "10". The amplitude is configured through the MAMPx[3:0] bits in the DAC\_CR register. An internal triangle counter is incremented three APB1 clock cycles after each trigger event. The value of this counter is then added to the DAC\_DHRx register without overflow and the sum is stored into the DAC\_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVE<sub>x</sub>[1:0] bits.

**Figure 70. DAC triangle wave generation**

**Figure 71. DAC conversion (SW trigger enabled) with triangle wave generation**

**Note:** The DAC trigger must be enabled for noise generation by setting the *TEN<sub>x</sub>* bit in the *DAC\_CR* register.  
The *MAMP<sub>x</sub>[3:0]* bits must be configured before enabling the DAC, otherwise they cannot be changed.

## 14.4 Dual DAC channel conversion

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time.

Eleven possible conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHR<sub>x</sub> registers if needed.

All modes are described in the paragraphs below.

#### 14.4.1 Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC\_DOR1 (three APB1 clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC\_DOR2 (three APB1 clock cycles later).

#### 14.4.2 Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as "01" and the same LFSR mask value in the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.

#### 14.4.3 Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as "01" and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.

#### 14.4.4 Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and the same maximum amplitude value in the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

#### 14.4.5 Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

#### 14.4.6 Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

In this configuration, one APB1 clock cycle later, the DHR1 and DHR2 registers are transferred into DAC\_DOR1 and DAC\_DOR2, respectively.

#### 14.4.7 Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Load the dual DAC channel data to the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC\_DOR1 and DAC\_DOR2, respectively (after three APB1 clock cycles).

#### 14.4.8 Simultaneous trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits
- Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

#### 14.4.9 Simultaneous trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “01” and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated.

At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

#### 14.4.10 Simultaneous trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and the same maximum amplitude value using the MAMPx[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

#### 14.4.11 Simultaneous trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

- Set the two DAC channel trigger enable bits TEN1 and TEN2
- Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
- Configure the two DAC channel WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits
- Load the dual DAC channel data into the desired DHR register (DAC\_DHR12RD, DAC\_DHR12LD or DAC\_DHR8RD)

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC\_DOR1 (three APB1 clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC\_DOR2 (three APB1 clock cycles later). Then the DAC channel2 triangle counter is updated.

## 14.5 DAC registers

Refer to [Section 1.1: List of abbreviations for registers](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

### 14.5.1 DAC control register (DAC\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

Bits 31:30 Reserved, must be kept at reset value.

Bits 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled

1: DAC channel2 DMA underrun interrupt enabled

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled

1: DAC channel2 DMA mode enabled

Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1

0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3

0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7

0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15

0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31

0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63

0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127

0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255

1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511

1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023

1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047

≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

00: wave generation disabled

01: Noise wave generation enabled

1x: Triangle wave generation enabled

*Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)*

Bits 21:19 **TSEL2[2:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

000: Timer 6 TRGO event

001: Timer 8 TRGO event

010: Timer 7 TRGO event

011: Timer 5 TRGO event

100: Timer 2 TRGO event

101: Timer 4 TRGO event

110: External line9

111: Software trigger

*Note: Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).*

Bit 18 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

0: DAC channel2 trigger disabled and data written into the DAC\_DHRx register are transferred one APB1 clock cycle later to the DAC\_DOR2 register

1: DAC channel2 trigger enabled and data from the DAC\_DHRx register are transferred three APB1 clock cycles later to the DAC\_DOR2 register

*Note: When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DOR2 register takes only one APB1 clock cycle.*

Bit 17 **BOFF2**: DAC channel2 output buffer disable

This bit is set and cleared by software to enable/disable DAC channel2 output buffer.

0: DAC channel2 output buffer enabled

1: DAC channel2 output buffer disabled

Bit 16 **EN2**: DAC channel2 enable

This bit is set and cleared by software to enable/disable DAC channel2.

0: DAC channel2 disabled

1: DAC channel2 enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.

0: DAC channel1 DMA Underrun Interrupt disabled

1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.

0: DAC channel1 DMA mode disabled

1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1  
 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3  
 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7  
 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15  
 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31  
 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63  
 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127  
 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255  
 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511  
 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023  
 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047  
 ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable

These bits are set and cleared by software.

00: wave generation disabled  
 01: Noise wave generation enabled  
 1x: Triangle wave generation enabled

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bits 5:3 **TSEL1[2:0]**: DAC channel1 trigger selection

These bits select the external event used to trigger DAC channel1.

000: Timer 6 TRGO event  
 001: Timer 8 TRGO event  
 010: Timer 7 TRGO event  
 011: Timer 5 TRGO event  
 100: Timer 2 TRGO event  
 101: Timer 4 TRGO event  
 110: External line9  
 111: Software trigger

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bit 2 **TEN1**: DAC channel1 trigger enable

This bit is set and cleared by software to enable/disable DAC channel1 trigger.

0: DAC channel1 trigger disabled and data written into the DAC\_DHRx register are transferred one APB1 clock cycle later to the DAC\_DOR1 register  
 1: DAC channel1 trigger enabled and data from the DAC\_DHRx register are transferred three APB1 clock cycles later to the DAC\_DOR1 register

*Note: When software trigger is selected, the transfer from the DAC\_DHRx register to the DAC\_DOR1 register takes only one APB1 clock cycle.*

Bit 1 **BOFF1**: DAC channel1 output buffer disable

This bit is set and cleared by software to enable/disable DAC channel1 output buffer.

0: DAC channel1 output buffer enabled  
 1: DAC channel1 output buffer disabled

Bit 0 **EN1**: DAC channel1 enable

This bit is set and cleared by software to enable/disable DAC channel1.

0: DAC channel1 disabled  
 1: DAC channel1 enabled

### 14.5.2 DAC software trigger register (DAC\_SWTRIGR)

Address offset: 0x04

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |         |         |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|---------|---------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18      | 17      | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |         |         |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2       | 1       | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    | SWTRIG2 | SWTRIG1 |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    | w       | w       |    |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger

This bit is set and cleared by software to enable/disable the software trigger.

0: Software trigger disabled

1: Software trigger enabled

*Note: This bit is cleared by hardware (one APB1 clock cycle later) once the DAC\_DHR2 register value has been loaded into the DAC\_DOR2 register.*

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set and cleared by software to enable/disable the software trigger.

0: Software trigger disabled

1: Software trigger enabled

*Note: This bit is cleared by hardware (one APB1 clock cycle later) once the DAC\_DHR1 register value has been loaded into the DAC\_DOR1 register.*

### 14.5.3 DAC channel1 12-bit right-aligned data holding register (DAC\_DHR12R1)

Address offset: 0x08

Reset value: 0x0000 0000

|          |    |    |    |                |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----------------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27             | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |                |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11             | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | DACC1DHR[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data

These bits are written by software which specifies 12-bit data for DAC channel1.

#### 14.5.4 DAC channel1 12-bit left aligned data holding register (DAC\_DHR12L1)

Address offset: 0x0C

Reset value: 0x0000 0000

|                |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18 | 17 | 16 |
| Reserved       |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3        | 2  | 1  | 0  |
| DACC1DHR[11:0] |    |    |    |    |    |    |    |    |    |    |    | Reserved |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |          |    |    |    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC1DHR[11:0]**: DAC channel1 12-bit left-aligned data

These bits are written by software which specifies 12-bit data for DAC channel1.

Bits 3:0 Reserved, must be kept at reset value.

#### 14.5.5 DAC channel1 8-bit right aligned data holding register (DAC\_DHR8R1)

Address offset: 0x10

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|---------------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23            | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7             | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    | DACC1DHR[7:0] |    |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    | rw            | rw | rw | rw | rw | rw | rw | rw |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DACC1DHR[7:0]**: DAC channel1 8-bit right-aligned data

These bits are written by software which specifies 8-bit data for DAC channel1.

### 14.5.6 DAC channel2 12-bit right aligned data holding register (DAC\_DHR12R2)

Address offset: 0x14

Reset value: 0x0000 0000

|          |    |    |    |                |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----------------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27             | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |                |    |    |    |    |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11             | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | DACC2DHR[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data

These bits are written by software which specifies 12-bit data for DAC channel2.

### 14.5.7 DAC channel2 12-bit left aligned data holding register (DAC\_DHR12L2)

Address offset: 0x18

Reset value: 0x0000 0000

|                |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18 | 17 | 16 |
| Reserved       |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3        | 2  | 1  | 0  |
| DACC2DHR[11:0] |    |    |    |    |    |    |    |    |    |    |    | Reserved |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |          |    |    |    |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC2DHR[11:0]**: DAC channel2 12-bit left-aligned data

These bits are written by software which specify 12-bit data for DAC channel2.

Bits 3:0 Reserved, must be kept at reset value.

### 14.5.8 DAC channel2 8-bit right-aligned data holding register (DAC\_DHR8R2)

Address offset: 0x1C

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|---------------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23            | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7             | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    | DACC2DHR[7:0] |    |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    | rw            | rw | rw | rw | rw | rw | rw | rw |

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DACC2DHR[7:0]**: DAC channel2 8-bit right-aligned data

These bits are written by software which specifies 8-bit data for DAC channel2.

### 14.5.9 Dual DAC 12-bit right-aligned data holding register (DAC\_DHR12RD)

Address offset: 0x20

Reset value: 0x0000 0000

|          |    |    |    |                |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----------------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27             | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    | DACC2DHR[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15       | 14 | 13 | 12 | 11             | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | DACC1DHR[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC2DHR[11:0]**: DAC channel2 12-bit right-aligned data

These bits are written by software which specifies 12-bit data for DAC channel2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data

These bits are written by software which specifies 12-bit data for DAC channel1.

### 14.5.10 DUAL DAC 12-bit left aligned data holding register (DAC\_DHR12LD)

Address offset: 0x24

Reset value: 0x0000 0000

|                |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |
|----------------|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|
| 31             | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19       | 18 | 17 | 16 |
| DACC2DHR[11:0] |    |    |    |    |    |    |    |    |    |    |    | Reserved |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |          |    |    |    |
| 15             | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3        | 2  | 1  | 0  |
| DACC1DHR[11:0] |    |    |    |    |    |    |    |    |    |    |    | Reserved |    |    |    |
| rw             | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |          |    |    |    |

Bits 31:20 **DACC2DHR[11:0]**: DAC channel2 12-bit left-aligned data

These bits are written by software which specifies 12-bit data for DAC channel2.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC1DHR[11:0]**: DAC channel1 12-bit left-aligned data

These bits are written by software which specifies 12-bit data for DAC channel1.

Bits 3:0 Reserved, must be kept at reset value.

### 14.5.11 DUAL DAC 8-bit right aligned data holding register (DAC\_DHR8RD)

Address offset: 0x28

Reset value: 0x0000 0000

|               |    |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
|---------------|----|----|----|----|----|----|----|---------------|----|----|----|----|----|----|----|
| 31            | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23            | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved      |    |    |    |    |    |    |    |               |    |    |    |    |    |    |    |
| 15            | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7             | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DACC2DHR[7:0] |    |    |    |    |    |    |    | DACC1DHR[7:0] |    |    |    |    |    |    |    |
| rw            | rw | rw | rw | rw | rw | rw | rw | rw            | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DACC2DHR[7:0]**: DAC channel2 8-bit right-aligned data

These bits are written by software which specifies 8-bit data for DAC channel2.

Bits 7:0 **DACC1DHR[7:0]**: DAC channel1 8-bit right-aligned data

These bits are written by software which specifies 8-bit data for DAC channel1.

### 14.5.12 DAC channel1 data output register (DAC\_DOR1)

Address offset: 0x2C

Reset value: 0x0000 0000

|          |    | rc_w1   |          |    |    |    |    |    |    |    |    |    |    |    |    |

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2

1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate)

Bits 28:14 Reserved, must be kept at reset value.

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1

1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bits 12:0 Reserved, must be kept at reset value.

### 14.5.15 DAC register map

[Table 76](#) summarizes the DAC registers.

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 15 Digital camera interface (DCMI)

This section applies to all STM32F4xx devices, unless otherwise specified.

### 15.1 DCMI introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

This interface is for use with black & white cameras, X24 and X5 cameras, and it is assumed that all pre-processing like resizing is performed in the camera module.

### 15.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14- bit progressive video: either monochrome or raw bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

### 15.3 DCMI pins

[Table 77](#) shows the DCMI pins.

**Table 77. DCMI pins**

| Name    | Signal type                      |
|---------|----------------------------------|
| D[0:13] | Data inputs                      |
| HSYNC   | Horizontal synchronization input |
| VSYNC   | Vertical synchronization input   |
| PIXCLK  | Pixel clock input                |

### 15.4 DCMI clocks

The digital camera interface uses two clock domains PIXCLK and HCLK. The signals generated with PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The minimum PIXCLK period must be higher than 2.5 HCLK periods.

## 15.5 DCMI functional overview

The digital camera interface is a synchronous parallel interface that can receive high-speed (up to 54 Mbytes/s) data flows. It consists of up to 14 data lines (D13-D0) and a pixel clock line (PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI\_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI\_CR register) must be set.

The data flow is synchronized either by hardware using the optional HSYNC (horizontal synchronization) and VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.

*Figure 72* shows the DCMI block diagram.

**Figure 72. DCMI block diagram**

Figure 73. Top-level block diagram

ai15603b

### 15.5.1 DMA interface

The DMA interface is active when the CAPTURE bit in the DCMI\_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

### 15.5.2 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits in the DCMI\_CR register. If less than 14 bits are used, the unused data pins must not be assigned to DCMI interface through GPIO alternate functions.

Table 78. DCMI signals

| Signal name |          | Signal description                      |
|-------------|----------|-----------------------------------------|
| 8 bits      | D[0..7]  | Data                                    |
| 10 bits     | D[0..9]  |                                         |
| 12 bits     | D[0..11] |                                         |
| 14 bits     | D[0..13] |                                         |
| PIXCLK      |          | Pixel clock                             |
| HSYNC       |          | Horizontal synchronization / Data valid |
| VSYNC       |          | Vertical synchronization                |

The data are synchronous with PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The HSYNC signal indicates the start/end of a line.

The VSYNC signal indicates the start/end of a frame

Figure 74. DCMI signal waveforms

1. The capture edge of DCMI\_PIXCLK is the falling edge, the active state of DCMI\_HSYNC and DCMI\_VSYNC is 1.

1. DCMI\_HSYNC and DCMI\_VSYNC can change states at the same time.

### 8-bit data

When EDM[1:0] in DCMI\_CR are programmed to “00” the interface captures 8 LSB’s at its input (D[0:7]) and stores them as 8-bit data. The D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4<sup>th</sup> captured data byte is placed in the MSB position in the 32-bit word. [Table 79](#) gives an example of the positioning of captured data bytes in two 32-bit words.

Table 79. Positioning of captured data bytes in 32-bit words (8-bit width)

| Byte address | 31:24          | 23:16          | 15:8           | 7:0            |
|--------------|----------------|----------------|----------------|----------------|
| 0            | $D_{n+3}[7:0]$ | $D_{n+2}[7:0]$ | $D_{n+1}[7:0]$ | $D_n[7:0]$     |
| 4            | $D_{n+7}[7:0]$ | $D_{n+6}[7:0]$ | $D_{n+5}[7:0]$ | $D_{n+4}[7:0]$ |

### 10-bit data

When EDM[1:0] in DCMI\_CR are programmed to “01”, the camera interface captures 10-bit data at its input D[0..9] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits in the DCMI\_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2<sup>nd</sup> captured data are placed in the MSB position in the 32-bit word as shown in [Table 80](#).

Table 80. Positioning of captured data bytes in 32-bit words (10-bit width)

| Byte address | 31:26 | 25:16          | 15:10 | 9:0            |
|--------------|-------|----------------|-------|----------------|
| 0            | 0     | $D_{n+1}[9:0]$ | 0     | $D_n[9:0]$     |
| 4            | 0     | $D_{n+3}[9:0]$ | 0     | $D_{n+2}[9:0]$ |

### 12-bit data

When EDM[1:0] in DCMI\_CR are programmed to “10”, the camera interface captures the 12-bit data at its input D[0..11] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2<sup>nd</sup> captured data are placed in the MSB position in the 32-bit word as shown in [Table 81](#).

**Table 81. Positioning of captured data bytes in 32-bit words (12-bit width)**

| Byte address | 31:28 | 27:16                   | 15:12 | 11:0                    |
|--------------|-------|-------------------------|-------|-------------------------|
| 0            | 0     | D <sub>n+1</sub> [11:0] | 0     | D <sub>n</sub> [11:0]   |
| 4            | 0     | D <sub>n+3</sub> [11:0] | 0     | D <sub>n+2</sub> [11:0] |

### 14-bit data

When EDM[1:0] in DCMI\_CR are programmed to “11”, the camera interface captures the 14-bit data at its input D[0..13] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2<sup>nd</sup> captured data are placed in the MSB position in the 32-bit word as shown in [Table 82](#).

**Table 82. Positioning of captured data bytes in 32-bit words (14-bit width)**

| Byte address | 31:30 | 29:16                   | 15:14 | 13:0                    |
|--------------|-------|-------------------------|-------|-------------------------|
| 0            | 0     | D <sub>n+1</sub> [13:0] | 0     | D <sub>n</sub> [13:0]   |
| 4            | 0     | D <sub>n+3</sub> [13:0] | 0     | D <sub>n+2</sub> [13:0] |

## 15.5.3 Synchronization

The digital camera interface supports embedded or hardware (HSYNC & VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI\_CR register, the EDM[1:0] bits should be cleared to “00”).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, VSYNC is used as a start/end of the image, and HSYNC is used as a Data Valid signal. [Figure 75](#) shows the corresponding timing diagram.

Figure 75. Timing diagram

## Hardware synchronization mode

In hardware synchronisation mode, the two synchronization signals (HSYNC/VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronisation periods. The HSYNC/VSYNC signals act like blanking signals since all the data received during HSYNC/VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the VSYNC signal. When the hardware synchronisation mode is selected, and capture is enabled (CAPTURE bit set in DCMI\_CR), data transfer is synchronized with the deactivation of the VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

## Embedded data synchronization mode

In this synchronisation mode, the data flow is synchronised using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are *not* used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI\_CR register, the EDM[1:0] bits should be programmed to "00"). For other data widths, this mode generates unpredictable results and must not be used.

*Note: Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).*

- Mode 2

Four embedded codes signal the following events

- Frame start (FS)
- Frame end (FE)
- Line start (LS)
- Line end (LE)

The XY values in the 0xFF0000XY format of the four codes are programmable (see [Section 15.8.7: DCMI embedded synchronization code register \(DCMI\\_ESCR\)](#)).

A 0xFF value programmed as a "frame end" means that all the unused codes are interpreted as valid frame end codes.

In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

- Mode 1

An alternative coding is the camera mode 1. This mode is ITU656 compatible.

The codes signal another set of events:

- SAV (active line) - line start
- EAV (active line) - line end
- SAV (blanking) - end of line during interframe blanking period
- EAV (blanking) - end of line during interframe blanking period

This mode can be supported by programming the following codes:

- $FS \leq 0xFF$
- $FE \leq 0xFF$
- $LS \leq SAV$  (active)
- $LE \leq EAV$  (active)

An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. You can therefore select a bit to compare in the embedded code and detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

### Example

$FS = 0xA5$

Unmask code for  $FS = 0x10$

In this case the frame start code is embedded in the bit 4 of the frame start code.

## 15.5.4 Capture modes

This interface supports two types of capture: snapshot (single frame) and continuous grab.

### Snapshot mode (single frame)

In this mode, a single frame is captured ( $CM = '1'$  in the `DCMI_CR` register). After the `CAPTURE` bit is set in `DCMI_CR`, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (`CAPTURE` bit cleared in `DCMI_CR`) after receiving the first complete frame. An interrupt is generated (`IT_FRAME`) if it is enabled.

In case of an overrun, the frame is lost and the `CAPTURE` bit is cleared.

**Figure 76. Frame capture waveforms in Snapshot mode**

1. Here, the active state of `DCMI_HSYNC` and `DCMI_VSYNC` is 1.
2. `DCMI_HSYNC` and `DCMI_VSYNC` can change states at the same time.

### Continuous grab mode

In this mode (CM bit = '0' in DCMI\_CR), once the CAPTURE bit has been set in DCMI\_CR, the grabbing process starts on the next VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI\_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.

**Figure 77. Frame capture waveforms in continuous grab mode**

1. Here, the active state of DCMI\_HSYNC and DCMI\_VSYNC is 1.
2. DCMI\_HSYNC and DCMI\_VSYNC can change states at the same time.

In continuous grab mode, you can configure the FCRC bits in DCMI\_CR to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

**Note:** *In the hardware synchronization mode (ESS = '0' in DCMI\_CR), the IT\_VSYNC interrupt is generated (if enabled) even when CAPTURE = '0' in DCMI\_CR so, to reduce the frame capture rate even further, the IT\_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.*

### 15.5.5 Crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI\_CWSTRT and DCMI\_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

Figure 78. Coordinates and size of the window after cropping

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.

If the VSYNC signal goes active before the number of lines is specified in the DCMI\_CWSIZE register, then the capture stops and an IT\_FRAME interrupt is generated when enabled.

Figure 79. Data capture waveforms

1. Here, the active state of DCMI\_HSYNC and DCMI\_VSYNC is 1.
2. DCMI\_HSYNC and DCMI\_VSYNC can change states at the same time.

### 15.5.6 JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit in the DCMI\_CR register. JPEG images are not stored as lines and frames, so the VSYNC signal is used to start the capture while HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4, you should therefore be careful when handling this case since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with '0s' and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in the JPEG format.

### 15.5.7 FIFO

A four-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.

## 15.6 Data format description

### 15.6.1 Data formats

Three types of data are supported:

- 8-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W, YCbCr or RGB data, the maximum input size is  $2048 \times 2048$  pixels. No limit in JPEG compressed mode.

For monochrome, RGB & YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little endian format is supported.

**Figure 80. Pixel raster scan order**

## 15.6.2 Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

[Table 83](#) shows how the data are stored.

**Table 83. Data storage in monochrome progressive video format**

| Byte address | 31:24 | 23:16 | 15:8  | 7:0   |
|--------------|-------|-------|-------|-------|
| 0            | n + 3 | n + 2 | n + 1 | n     |
| 4            | n + 7 | n + 6 | n + 5 | n + 4 |

## 15.6.3 RGB format

Characteristics:

- Raster format
- RGB
- Interleaved: one buffer: R, G & B interleaved: BRGBRBRG, etc.
- Optimized for display output

The RGB planar format is compatible with standard OS frame buffer display formats.

Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and grayscale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

[Table 84](#) shows how the data are stored.

**Table 84. Data storage in RGB progressive video format**

| Byte address | 31:27     | 26:21       | 20:16      | 15:11     | 10:5        | 4:0        |
|--------------|-----------|-------------|------------|-----------|-------------|------------|
| 0            | Red n + 1 | Green n + 1 | Blue n + 1 | Red n     | Green n     | Blue n     |
| 4            | Red n + 4 | Green n + 3 | Blue n + 3 | Red n + 2 | Green n + 2 | Blue n + 2 |

## 15.6.4 YCbCr format

Characteristics:

- Raster format
- YCbCr 4:2:2
- Interleaved: one Buffer: Y, Cb & Cr interleaved: CbYCrYCbYCr, etc.

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in [Table 85](#).

Table 85. Data storage in YCbCr progressive video format

| Byte address | 31:24     | 23:16      | 15:8      | 7:0        |
|--------------|-----------|------------|-----------|------------|
| 0            | $Y_{n+1}$ | $Cr_n$     | $Y_n$     | $Cb_n$     |
| 4            | $Y_{n+3}$ | $Cr_{n+2}$ | $Y_{n+2}$ | $Cb_{n+2}$ |

## 15.7 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (IT\_DCMI) is the OR of all the individual interrupts. [Table 86](#) gives the list of all interrupts.

Table 86. DCMI interrupts

| Interrupt name | Interrupt event                                                                     |
|----------------|-------------------------------------------------------------------------------------|
| IT_LINE        | Indicates the end of line                                                           |
| IT_FRAME       | Indicates the end of frame capture                                                  |
| IT_OVR         | indicates the overrun of data reception                                             |
| IT_VSYNC       | Indicates the synchronization frame                                                 |
| IT_ERR         | Indicates the detection of an error in the embedded synchronization frame detection |
| IT_DCMI        | Logic OR of the previous interrupts                                                 |

## 15.8 DCMI register description

All DCMI registers have to be accessed as 32-bit words, otherwise a bus error occurs.

### 15.8.1 DCMI control register 1 (DCMI\_CR)

Address offset: 0x00

Reset value: 0x0000 0x0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |          |     |    |      |   |       |       |        |     |      |      |    |         |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----------|-----|----|------|---|-------|-------|--------|-----|------|------|----|---------|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14     | 13       | 12  | 11 | 10   | 9 | 8     | 7     | 6      | 5   | 4    | 3    | 2  | 1       | 0  |    |    |    |    |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | ENABLE | Reserved | EDM |    | FCRC |   | VSPOL | HSPOL | PCKPOL | ESS | JPEG | CROP | CM | CAPTURE |    |    |    |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |          |     |    |      |   |       |       |        |     |      |      |    |         | rw | rw | rw | rw | rw |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |          |     |    |      |   |       |       |        |     |      |      |    |         |    |    |    |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |        |          |     |    |      |   |       |       |        |     |      |      |    |         |    |    |    |    |    |

Bit 31:15 Reserved, must be kept at reset value.

Bit 14 **ENABLE**: DCMI enable

0: DCMI disabled

1: DCMI enabled

*Note: The DCMI configuration registers should be programmed correctly before enabling this Bit*

Bit 13: 12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]**: Extended data mode

- 00: Interface captures 8-bit data on every pixel clock
- 01: Interface captures 10-bit data on every pixel clock
- 10: Interface captures 12-bit data on every pixel clock
- 11: Interface captures 14-bit data on every pixel clock

Bits 9:8 **FCRC[1:0]**: Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.

- 00: All frames are captured
- 01: Every alternate frame captured (50% bandwidth reduction)
- 10: One frame in 4 frames captured (75% bandwidth reduction)
- 11: reserved

Bit 7 **VSPOL**: Vertical synchronization polarity

This bit indicates the level on the VSYNC pin when the data are not valid on the parallel interface.

- 0: VSYNC active low
- 1: VSYNC active high

Bit 6 **HSPOL**: Horizontal synchronization polarity

This bit indicates the level on the HSYNC pin when the data are not valid on the parallel interface.

- 0: HSYNC active low
- 1: HSYNC active high

Bit 5 **PCKPOL**: Pixel clock polarity

This bit configures the capture edge of the pixel clock

- 0: Falling edge active.
- 1: Rising edge active.

Bit 4 **ESS**: Embedded synchronization select

- 0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the HSYNC/VSYNC signals.
- 1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.

*Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.*

This bit is disabled in JPEG mode.

Bit 3 **JPEG**: JPEG format

- 0: Uncompressed video format
- 1: This bit is used for JPEG data transfers. The HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bits 2 **CROP**: Crop feature

- 0: The full image is captured. In this case the total number of bytes in an image frame should be a multiple of 4
- 1: Only the data inside the window specified by the crop register will be captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM**: Capture mode

0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.

1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.

Bit 0 **CAPTURE**: Capture enable

0: Capture disabled.

1: Capture enabled.

The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.

In snapshot mode, the CAPTURE bit is automatically cleared at the end of the 1st frame received.

In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit will be effectively cleared after the frame end.

*Note: The DMA controller and all DCMI configuration registers should be programmed correctly before enabling this bit.*

Address offset: 0x04

Reset value: 0x0000 0x0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |     |       |       |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|-----|-------|-------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2   | 1     | 0     |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   | FNE | VSYNC | HSYNC |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   | r   | r     | r     |

Bit 2 **FNE**: FIFO not empty

1: FIFO contains valid data

0: FIFO empty

This bit gives the state of the VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:

0: active frame

1: synchronization between frames

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI CR is set.

This bit gives the state of the HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:

0: active line

1: synchronization between lines

In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI\_CR is set.

### 15.8.3 DCMI raw interrupt status register (DCMI\_RIS)

Address offset: 0x08

Reset value: 0x0000 0x0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |          |           |         |         |           |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|----------|-----------|---------|---------|-----------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3        | 2         | 1       | 0       |           |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | LINE_RIS | VSYNC_RIS | ERR_RIS | OVR_RIS | FRAME_RIS |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | r        | r         | r       | r       | r         |

DCMI\_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI\_IER register value.

Bits 31:5 Reserved, must be kept at reset value.

**Bit 4 LINE\_RIS:** Line raw interrupt status

This bit gets set when the HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI\_CR is set.

It is cleared by writing a '1' to the LINE\_ISC bit in DCMI\_ICR.

**Bit 3 VSYNC\_RIS:** VSYNC raw interrupt status

This bit is set when the VSYNC signal changes from the inactive state to the active state.

In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI\_CR.

It is cleared by writing a '1' to the VSYNC\_ISC bit in DCMI\_ICR.

**Bit 2 ERR\_RIS:** Synchronization error raw interrupt status

0: No synchronization error detected

1: Embedded synchronization characters are not received in the correct order.

This bit is valid only in the embedded synchronization mode. It is cleared by writing a '1' to the ERR\_ISC bit in DCMI\_ICR.

*Note: This bit is available only in embedded synchronization mode.*

**Bit 1 OVR\_RIS:** Overrun raw interrupt status

0: No data buffer overrun occurred

1: A data buffer overrun occurred and the data FIFO is corrupted.

This bit is cleared by writing a '1' to the OVR\_ISC bit in DCMI\_ICR.

**Bit 0 FRAME\_RIS:** Capture complete raw interrupt status

0: No new capture

1: A frame has been captured.

This bit is set when a frame or window has been captured.

In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (e.g. window cropped outside the frame).

This bit is cleared by writing a '1' to the FRAME\_ISC bit in DCMI\_ICR.

### 15.8.4 DCMI interrupt enable register (DCMI\_IER)

Address offset: 0x0C

Reset value: 0x0000 0x0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |         |          |        |        |          |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---------|----------|--------|--------|----------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3       | 2        | 1      | 0      |          |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | LINE_IE | VSYNC_IE | ERR_IE | OVR_IE | FRAME_IE |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   | RW      | RW       | RW     | RW     | RW       |

The DCMI\_IER register is used to enable interrupts. When one of the DCMI\_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **LINE\_IE**: Line interrupt enable

0: No interrupt generation when the line is received

1: An interrupt is generated when a line has been completely received

Bit 3 **VSYNC\_IE**: VSYNC interrupt enable

0: No interrupt generation

1: An interrupt is generated on each VSYNC transition from the inactive to the active state

The active state of the VSYNC signal is defined by the VSPOL bit.

Bit 2 **ERR\_IE**: Synchronization error interrupt enable

0: No interrupt generation

1: An interrupt is generated if the embedded synchronization codes are not received in the correct order.

*Note: This bit is available only in embedded synchronization mode.*

Bit 1 **OVR\_IE**: Overrun interrupt enable

0: No interrupt generation

1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received.

Bit 0 **FRAME\_IE**: Capture complete interrupt enable

0: No interrupt generation

1: An interrupt is generated at the end of each received frame/crop window (in crop mode).

### 15.8.5 DCMI masked interrupt status register (DCMI\_MIS)

This DCMI\_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI\_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI\_IER is set and the corresponding bit in DCMI\_RIS is set.

Address offset: 0x10

Reset value: 0x0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Bits 31:5 Reserved, must be kept at reset value.

**Bit 4 LINE\_MIS:** Line masked interrupt status

This bit gives the status of the masked line interrupt

0: No interrupt generation when the line is received

1: An Interrupt is generated when a line has been completely received and the LINE\_IE bit is set in DCMI\_IER.

**Bit 3 VSYNC\_MIS:** VSYNC masked interrupt status

This bit gives the status of the masked VSYNC interrupt

0: No interrupt is generated on VSYNC transitions

1: An interrupt is generated on each VSYNC transition from the inactive to the active state and the VSYNC\_IE bit is set in DCMI\_IER.

The active state of the VSYNC signal is defined by the VSPOL bit.

**Bit 2 ERR\_MIS:** Synchronization error masked interrupt status

This bit gives the status of the masked synchronization error interrupt

0: No interrupt is generated on a synchronization error

1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR\_IE bit in DCMI\_IER is set.

*Note: This bit is available only in embedded synchronization mode.*

**Bit 1 OVR\_MIS:** Overrun masked interrupt status

This bit gives the status of the masked overflow interrupt

0: No interrupt is generated on overrun

1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR\_IE bit is set in DCMI\_IER.

**Bit 0 FRAME\_MIS:** Capture complete masked interrupt status

This bit gives the status of the masked capture complete interrupt

0: No interrupt is generated after a complete capture

1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME\_IE bit is set in DCMI\_IER.

15.8.6 DCMI interrupt clear register (DCMI\_ICR)

Address offset: 0x14

Reset value: 0x0000 0x0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |          |           |         |         |           |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|----------|-----------|---------|---------|-----------|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5        | 4         | 3       | 2       | 1         | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   | LINE_ISC | VSYNC_ISC | ERR_ISC | OVR_ISC | FRAME_ISC |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   | W        | W         | W       | W       | W         |   |

The DCMI\_ICR register is write-only. Writing a ‘1’ into a bit of this register clears the corresponding bit in the DCMI\_RIS and DCMI\_MIS registers. Writing a ‘0’ has no effect.

- Bits 15:5 Reserved, must be kept at reset value.
- Bit 4 **LINE\_ISC**: line interrupt status clear  
Writing a ‘1’ into this bit clears LINE\_RIS in the DCMI\_RIS register
- Bit 3 **VSYNC\_ISC**: Vertical synch interrupt status clear  
Writing a ‘1’ into this bit clears the VSYNC\_RIS bit in DCMI\_RIS
- Bit 2 **ERR\_ISC**: Synchronization error interrupt status clear  
Writing a ‘1’ into this bit clears the ERR\_RIS bit in DCMI\_RIS  
*Note: This bit is available only in embedded synchronization mode.*
- Bit 1 **OVR\_ISC**: Overrun interrupt status clear  
Writing a ‘1’ into this bit clears the OVR\_RIS bit in DCMI\_RIS
- Bits 0 **FRAME\_ISC**: Capture complete interrupt status clear  
Writing a ‘1’ into this bit clears the FRAME\_RIS bit in DCMI\_RIS

### 15.8.7 DCMI embedded synchronization code register (DCMI\_ESCR)

Address offset: 0x18

Reset value: 0x0000 0x0000

|     |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23  | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15  | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7   | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| FEC |    |    |    |    |    |    |    | LEC |    |    |    |    |    |    |    | LSC |    |    |    |    |    |    |    | FSC |    |    |    |    |    |    |    |
| rW  | rW | rW | rW | rW | rW | rW | rW | rW  | rW | rW | rW | rW | rW | rW | rW | rW  | rW | rW | rW | rW | rW | rW | rW | rW  | rW | rW | rW | rW | rW | rW | rW |

Bits 31:24 **FEC**: Frame end delimiter code

This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.

If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC**: Line end delimiter code

This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC**: Line start delimiter code

This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC**: Frame start delimiter code

This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.

If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the 1<sup>st</sup> occurrence of LSC after an FEC code will be interpreted as a start of frame delimiter.

### 15.8.8 DCMI embedded synchronization unmask register (DCMI\_ESUR)

Address offset: 0x1C

Reset value: 0x0000 0x0000

|     |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |     |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|-----|----|----|----|----|----|----|----|
| 31  | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23  | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15  | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7   | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| FEU |    |    |    |    |    |    |    | LEU |    |    |    |    |    |    |    | LSU |    |    |    |    |    |    |    | FSU |    |    |    |    |    |    |    |
| rw  | rw | rw | rw | rw | rw | rw | rw | rw  | rw | rw | rw | rw | rw | rw | rw | rw  | rw | rw | rw | rw | rw | rw | rw | rw  | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 **FEU**: Frame end delimiter unmask

This byte specifies the mask to be applied to the code of the frame end delimiter.

0: The corresponding bit in the FEC byte in DCMI\_ESCR is masked while comparing the frame end delimiter with the received data.

1: The corresponding bit in the FEC byte in DCMI\_ESCR is compared while comparing the frame end delimiter with the received data

Bits 23:16 **LEU**: Line end delimiter unmask

This byte specifies the mask to be applied to the code of the line end delimiter.

0: The corresponding bit in the LEC byte in DCMI\_ESCR is masked while comparing the line end delimiter with the received data

1: The corresponding bit in the LEC byte in DCMI\_ESCR is compared while comparing the line end delimiter with the received data

Bits 15:8 **LSU**: Line start delimiter unmask

This byte specifies the mask to be applied to the code of the line start delimiter.

0: The corresponding bit in the LSC byte in DCMI\_ESCR is masked while comparing the line start delimiter with the received data

1: The corresponding bit in the LSC byte in DCMI\_ESCR is compared while comparing the line start delimiter with the received data

Bits 7:0 **FSU**: Frame start delimiter unmask

This byte specifies the mask to be applied to the code of the frame start delimiter.

0: The corresponding bit in the FSC byte in DCMI\_ESCR is masked while comparing the frame start delimiter with the received data

1: The corresponding bit in the FSC byte in DCMI\_ESCR is compared while comparing the frame start delimiter with the received data

### 15.8.9 DCMI crop window start (DCMI\_CWSTRT)

Address offset: 0x20

Reset value: 0x0000 0x0000

|          |    |    |           |     |     |     |     |     |     |     |     |     |     |     |     |     |          |               |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------|----|----|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|----------|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **VST[12:0]**: Vertical start line count

The image capture starts with this line number. Previous line data are ignored.

0x0000 => line 1

0x0001 => line 2

0x0002 => line 3

....

Bits 15:14 Reserved, must be kept at reset value.

Bit 13:0 **HOFFCNT[13:0]**: Horizontal offset count

This value gives the number of pixel clocks to count before starting a capture.

### 15.8.10 DCMI crop window size (DCMI\_CWSIZE)

Address offset: 0x24

Reset value: 0x0000 0x0000

|          |    |             |     |     |     |     |     |     |     |     |     |     |     |     |     |          |    |              |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **VLINE[13:0]**: Vertical line count

This value gives the number of lines to be captured from the starting point.

0x0000 => 1 line

0x0001 => 2 lines

0x0002 => 3 lines

....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **CAPCNT[13:0]**: Capture count

This value gives the number of pixel clocks to be captured from the starting point on the same line. It value should corresponds to word-aligned data for different widths of parallel interfaces.

0x0000 => 1 pixel

0x0001 => 2 pixels

0x0002 => 3 pixels

....

### 15.8.11 DCMI data register (DCMI\_DR)

Address offset: 0x28

Reset value: 0x0000 0x0000

|       |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |       |    |    |    |    |    |   |   |       |   |   |   |   |   |   |   |
|-------|----|----|----|----|----|----|----|-------|----|----|----|----|----|----|----|-------|----|----|----|----|----|---|---|-------|---|---|---|---|---|---|---|
| 31    | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23    | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15    | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Byte3 |    |    |    |    |    |    |    | Byte2 |    |    |    |    |    |    |    | Byte1 |    |    |    |    |    |   |   | Byte0 |   |   |   |   |   |   |   |
| r     | r  | r  | r  | r  | r  | r  | r  | r     | r  | r  | r  | r  | r  | r  | r  | r     | r  | r  | r  | r  | r  | r | r | r     | r | r | r | r | r | r | r |

Bits 31:24 Data byte 3

Bits 23:16 Data byte 2

Bits 15:8 Data byte 1

Bits 7:0 Data byte 0

The digital camera Interface packages all the received data in 32-bit format before requesting a DMA transfer. A 4-word deep FIFO is available to leave enough time for DMA transfers and avoid DMA overrun conditions.

### 15.8.12 DCMI register map

[Table 87](#) summarizes the DCMI registers.

**Table 87. DCMI register map and reset values**

| Offset | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15     | 14       | 13  | 12 | 11  | 10 | 9     | 8     | 7      | 6   | 5    | 4    | 3  | 2        | 1         | 0       |         |           |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 16 LCD-TFT controller (LTDC)

This section applies only to STM32F429xx/439xx devices.

### 16.1 Introduction

The LCD-TFT (Liquid Crystal Display - Thin Film Transistor) display controller provides a parallel digital RGB (Red, Green, Blue) and signals for horizontal, vertical synchronisation, Pixel Clock and Data Enable as output to interface directly to a variety of LCD and TFT panels.

### 16.2 LTDC main features

- 24-bit RGB Parallel Pixel Output; 8 bits-per-pixel (RGB888)
- 2 display layers with dedicated FIFO (64x32-bit)
- Color Look-Up Table (CLUT) up to 256 color (256x24-bit) per layer
- Supports up to XGA (1024x768) resolution
- Programmable timings for different display panels
- Programmable Background color
- Programmable polarity for HSync, VSync and Data Enable
- Up to 8 Input color formats selectable per layer
  - ARGB8888
  - RGB888
  - RGB565
  - ARGB1555
  - ARGB4444
  - L8 (8-bit Luminance or CLUT)
  - AL44 (4-bit alpha + 4-bit luminance)
  - AL88 (8-bit alpha + 8-bit luminance)
- Pseudo-random dithering output for low bits per channel
  - Dither width 2-bits for Red, Green, Blue
- Flexible blending between two layers using alpha value (per pixel or constant)
- Color Keying (transparency color)
- Programmable Window position and size
- Supports thin film transistor (TFT) color displays
- AHB master interface with burst of 16 words
- Up to 4 programmable interrupt events

## 16.3 LTDC functional description

### 16.3.1 LTDC block diagram

The block diagram of the LTDC is shown in [Figure 81: LTDC block diagram](#).

**Figure 81. LTDC block diagram**

Layer FIFO: One FIFO 64x32 bit per layer.

PFC: Pixel Format Converter performing the pixel format conversion from the selected input pixel format of a layer to words.

AHB interface: For data transfer from memories to the FIFO.

Blending, Dithering unit and Timings Generator: Refer to [Section 16.4.1](#) and [Section 16.4.2](#).

### 16.3.2 LTDC reset and clocks

The LCD-TFT controller peripheral uses 3 clock domains:

- The AHB clock domain (HCLK) is used for data transfer from the memories to the Layer FIFO and frame buffer configuration register
- The APB2 clock domain (PCLK2) is used for global configuration register and interrupt registers
- The Pixel Clock domain (LCD\_CLK) is used to generate LCD-TFT interface signals, pixel data generation and layer configuration. The LCD\_CLK output should be configured following the panel requirements. The LCD\_CLK is configured through the PLLSAI (refer to RCC section).

[Table 88](#) summarizes the clock domain for each register.

Table 88. LTDC registers versus clock domain

| LTDC registers | Clock domain          |
|----------------|-----------------------|
| LTDC_LxCR      | HCLK                  |
| LTDC_LxCFBAR   |                       |
| LTDC_LxCFBLR   |                       |
| LTDC_LxCFBLNR  |                       |
| LTDC_SRCR      | PCLK2                 |
| LTDC_IER       |                       |
| LTDC_ISR       |                       |
| LTDC_ICR       |                       |
| LTDC_SSCR      | Pixel Clock (LCD_CLK) |
| LTDC_BPCR      |                       |
| LTDC_AWCR      |                       |
| LTDC_TWCR      |                       |
| LTDC_GCR       |                       |
| LTDC_BCCR      |                       |
| LTDC_LIPCR     |                       |
| LTDC_CPSR      |                       |
| LTDC_CDSR      |                       |
| LTDC_LxWHPCR   |                       |
| LTDC_LxWVPCR   |                       |
| LTDC_LxCKCR    |                       |
| LTDC_LxPFCR    |                       |
| LTDC_LxCACR    |                       |
| LTDC_LxDCCR    |                       |
| LTDC_LxBFCR    |                       |
| LTDC_LxCLUTWR  |                       |

Care must be taken when accessing the LTDC registers since the APB2 bus is stalling when the following operations are ongoing:

- Register write access and update for 6 xPCKL2 period + 5x LCD\_CLK period (5x HCLK period for register on AHB clock domain)
- Register read access for 7xPCKL2 period + 5x LCD\_CLK period (5x HCLK period for register on AHB clock domain).

For registers on PCLK2 clock domain, APB2 bus is stalling during the register write access for 6 xPCKL2 period and 7xPCKL2 period for read access.

The LCD controller can be reset by setting the corresponding bit in the RCC\_APB2RSTR register. It resets the three clock domains.

### 16.3.3 LCD-TFT pins and signal interface

The Table below summarizes the LTDC signal interface:

**Table 89. LCD-TFT pins and signal interface**

| LCD-TFT signals | I/O | Description                |
|-----------------|-----|----------------------------|
| LCD_CLK         | O   | Clock Output               |
| LCD_HSYNC       | O   | Horizontal Synchronization |
| LCD_VSYNC       | O   | Vertical Synchronization   |
| LCD_DE          | O   | Not Data Enable            |
| LCD_R[7:0]      | O   | Data: 8-bit Red data       |
| LCD_G[7:0]      | O   | Data: 8-bit Green data     |
| LCD_B[7:0]      | O   | Data: 8-bit Blue data      |

The LCD-TFT controller pins must be configured by the user application. The unused pins can be used for other purposes.

For LTDC outputs up to 24-bit (RGB888), if less than 8bpp are used to output for example RGB565 or RGB666 to interface on 16b-bit or 18-bit displays, the RGB display data lines must be connected to the MSB of the LCD-TFT controller RGB data lines. As an example, in the case of an LCD-TFT controller interfacing with a RGB565 16-bit display, the LCD display R[4:0], G[5:0] and B[4:0] data lines pins must be connected to LCD-TFT controller LCD\_R[7:3], LCD\_G[7:2] and LCD\_B[7:3].

## 16.4 LTDC programmable parameters

The LCD-TFT controller provides flexible configurable parameters. It can be enabled or disabled through the **LTDC\_GCR** register.

### 16.4.1 LTDC Global configuration parameters

#### Synchronous Timings:

[Figure 82](#) presents the configurable timing parameters generated by the Synchronous Timings Generator block presented in the block diagram [Figure 81](#). It generates the Horizontal and Vertical Synchronization timings panel signals, the Pixel Clock and the Data Enable signals.

Figure 82. LCD-TFT Synchronous timings

**Note:** The HBP and HFP are respectively the Horizontal back porch and front porch period.  
The VBP and the VFP are respectively the Vertical back porch and front porch period.

The LCD-TFT programmable synchronous timings are:

- HSYNC and VSYNC Width: Horizontal and Vertical Synchronization width configured by programming a value of **HSYNC Width - 1** and **VSYNC Width - 1** in the **LTDC\_SSCR** register.
- HBP and VBP: Horizontal and Vertical Synchronization back porch width configured by programming the accumulated value **HSYNC Width + HBP - 1** and the accumulated value **VSYNC Width + VBP - 1** in the **LTDC\_BPCR** register.
- Active Width and Active Height: The Active Width and Active Height are configured by programming the accumulated value **HSYNC Width + HBP + Active Width - 1** and the accumulated value **VSYNC Width + VBP + Active Height - 1** in the **LTDC\_AWCR** register (only up to 1024x768 is supported).
- Total Width: The Total width is configured by programming the accumulated value **HSYNC Width + HBP + Active Width + HFP - 1** in the **LTDC\_TWCR** register. The HFP is the Horizontal front porch period.
- Total Height: The Total Height is configured by programming the accumulated value **VSYNC Height + VBP + Active Height + VFP - 1** in the **LTDC\_TWCR** register. The VFP is the Vertical front porch period.

**Note:** When the LTDC is enabled, the timings generated start with X/Y=0/0 position as the first horizontal synchronization pixel in the vertical synchronization area and following the back porch, active data display area and the front porch.

When the LTDC is disabled, the timing generator block is reset to  $X = \text{Total Width} - 1$ ,  $Y = \text{Total Height} - 1$  and held the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore only blanking data is output continuously.

### Example of Synchronous timings configuration

TFT-LCD timings (should be extracted from Panel datasheet):

- Horizontal and Vertical Synchronization width: 0x8 pixels and 0x4 lines
- Horizontal and Vertical back porch: 0x7 pixels and 0x2 lines
- Active Width and Active Height: 0x280 pixels, 0x1E0 lines (640x480)
- Horizontal front porch: 0x6 pixels
- Vertical front porch: 0x2 lines

The programmed values in the LTDC Timings registers will be:

- **LTDC\_SSCR** register: to be programmed to 0x00070003. (HSW[11:0] is 0x7 and VSH[10:0] is 0x3)
- **LTDC\_BPCR** register: to be programmed to 0x000E0005. (AHBP[11:0] is 0xE(0x8 + 0x6) and AVBP[10:0] is 0x5(0x4 + 0x1))
- **LTDC\_AWCR** register: to be programmed to 0x028E01E5. (AAW[11:0] is 0x28E(0x8 + 0x7 + 0x27F) and AAH[10:0] is 0x1E5(0x4 + 0x2 + 0x1DF))
- **LTDC\_TWCR** register: to be programmed to 0x00000294. (TOTALW[11:0] is 0x294(0x8 + 0x7 + 0x280 + 0x5))
- **LTDC\_THCR** register: to be programmed to 0x000001E7. (TOTALH[10:0] is 0x1E7(0x4 + 0x2 + 0x1E0 + 1))

### Programmable polarity

The Horizontal and Vertical Synchronization, Data Enable and Pixel Clock output signals polarity can be programmed to active high or active low through the **LTDC\_GCR** register.

### Background Color

A constant background color (RGB888) can be programmed through the **LTDC\_BCCR** register. It is used for blending with the bottom layer.

### Dithering

The Dithering pseudo-random technique using an LFSR is used to add a small random value (threshold) to each pixel color channel (R, G or B) value, thus rounding up the MSB in some cases when displaying a 24-bit data on 18-bit display. Thus the Dithering technique is used to round data which is different from one frame to the other.

The Dither pseudo-random technique is the same as comparing LSBs against a threshold value and adding a 1 to the MSB part only, if the LSB part is  $\geq$  the threshold. The LSBs are typically dropped once dithering was applied.

The width of the added pseudo-random value is 2 bits for each color channel; 2 bits for Red, 2 bits for Green and 2 bits for Blue.

Once the LCD-TFT controller is enabled, the LFSR starts running with the first active pixel and it is kept running even during blanking periods and when dithering is switched off. If the LTDC is disabled, the LFSR is reset.

The Dithering can be switched On and Off on the fly through the **LTDC\_GCR** register.

### Reload Shadow registers

Some configuration registers are shadowed. The shadow registers values can be reloaded immediately to the active registers when writing to these registers or at the beginning of the vertical blanking period following the configuration in the **LTDC\_SRCR** register. If the immediate reload configuration is selected, the reload should be only activated when all new registers have been written.

The shadow registers should not be modified again before the reload has been done. Reading from the shadow registers returns the actual active value. The new written value can only be read after the reload has taken place.

A register reload interrupt can be generated if enabled in the **LTDC\_IER** register.

The shadowed registers are all the Layer 1 and Layer 2 registers except the **LTDC\_LxCLUTWR** register.

### Interrupt generation event

Refer to [Section 16.5: LTDC interrupts](#) for interrupt configuration.

## 16.4.2 Layer programmable parameters

Up to two layers can be enabled, disabled and configured separately. The layer display order is fixed and it is bottom up. If two layers are enabled, the Layer2 is the top displayed window.

### Windowing

Every layer can be positioned and resized and it must be inside the Active Display area.

The window position and size are configured through the top-left and bottom-right X/Y positions and the Internal timing generator which includes the synchronous, back porch size and the active data area. Refer to **LTDC\_LxWHPCR** and **LTDC\_WVPCR** registers.

The programmable layer position and size defines the first/last visible pixel of a line and the first/last visible line in the window. It allows to display either the full image frame or only a part of the image frame. Refer to [Figure 83](#)

- The first and the last visible pixel in the layer are set by configuring the WHSTPOS[11:0] and WHSPPOS[11:0] in the **LTDC\_LxWHPCR** register.
- The first and the last visible lines in the layer are set by configuring the WVSTPOS[10:0] and WVSPPOS[10:0] in the **LTDC\_LxWVPCR** register.

Figure 83. Layer window programmable parameters:

### Pixel input Format

The programmable pixel format is used for the data stored in the frame buffer of a layer.

Up to 8 input pixel formats can be configured for every layer through the **LTDC\_LxPFCR** register

The pixel data is read from the frame buffer and then transformed to the internal 8888 (ARGB) format as follows:

- Components which have a width of less than 8 bits get expanded to 8 bits by bit replication. The selected bit range is concatenated multiple times until it is longer than 8 bits. Of the resulting vector, the 8 MSB bits are chosen. Example: 5 bits of an RGB565 red channel become (bit positions): 43210432 (the 3 LSBs are filled with the 3 MSBs of the 5 bits)

The figure below describes the pixel data mapping depending on the selected format.

Table 90. Pixel Data mapping versus Color Format

| ARGB8888                           |                                    |                            |                          |

### Color Look-Up Table (CLUT)

The CLUT can be enabled at run-time for every layer through the **LTDC\_LxCR** register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT has to be loaded with the R, G and B values that will replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address which is the position within the CLUT.

The R, G and B values and their own respective address are programmed through the **LTDC\_LxCLUTWR** register.

- In case of L8 and AL88 input pixel format, the CLUT has to be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the **LTDC\_LxCLUTWR** register.
- In case of AL44 input pixel format, the CLUT has to be only loaded by 16 colors. The address of each color must be filled by replicating the 4-bit L channel to 8-bit as follows:
  - L0 (indexed color 0), at address 0x00
  - L1, at address 0x11
  - L2, at address 0x22
  - .....
  - L15, at address 0xFF

### Color Frame Buffer Address

Every Layer has a start address for the color frame buffer configured through the **LTDC\_LxCFBAR** register.

When a layer is enabled, the data is fetched from the Color Frame Buffer.

### Color Frame Buffer Length

Every layer has a total line length setting for the color frame buffer in bytes and a number of lines in the frame buffer configurable in the **LTDC\_LxCFBLR** and **LTDC\_LxCFBLNR** register respectively.

The line length and the number of lines settings are used to stop the prefetching of data to the layer FIFO at the end of the frame buffer.

- If it is set to less bytes than required, a FIFO underrun interrupt is generated if it has been previously enabled.
- If it is set to more bytes than actually required, the useless data read from the FIFO is discarded. The useless data is not displayed.

### Color Frame Buffer Pitch

Every layer has a configurable pitch for the color frame buffer, which is the distance between the start of one line and the beginning of the next line in bytes. It is configured through the **LTDC\_LxCFBLR** register.

### Layer Blending

The blending is always active and the two layers can be blended following the blending factors configured through the **LTDC\_LxBFCR** register.

The blending order is fixed and it is bottom up. If two layers are enabled, first the Layer1 is blended with the Background color, then the Layer2 is blended with the result of blended color of Layer1 and the background. Refer to [Figure 84](#).

Figure 84. Blending two layers with background

### Default color

Every layer can have a default color in the format ARGB which is used outside the defined layer window or when a layer is disabled.

The default color is configured through the **LTDC\_LxDCCR** register.

The blending is always performed between the two layers even when a layer is disabled. To avoid displaying the default color when a layer is disabled, keep the blending factors of this layer in the LTDC\_LxBFCR register to their reset value.

### Color Keying

A color key (RGB) can be configured to be representative for a transparent pixel.

If the Color Keying is enabled, the current pixels (after format conversion and before blending) are compared to the color key. If they match for the programmed RGB value, all channels (ARGB) of that pixel are set to 0.

The Color Key value can be configured and used at run-time to replace the pixel RGB value.

The Color Keying is enabled through the **LTDC\_LxCKCR** register.

## 16.5 LTDC interrupts

The LTDC provides four maskable interrupts logically ORed to two interrupt vectors.

The interrupt sources can be enabled or disabled separately through the **LTDC\_IER** register. Setting the appropriate mask bit to 1 enables the corresponding interrupt.

The two interrupts are generated on the following events:

- Line interrupt: generated when a programmed line is reached. The line interrupt position is programmed in the LTDC\_LIPCR register
- Register Reload interrupt: generated when the shadow registers reload was performed during the vertical blanking period
- FIFO Underrun interrupt: generated when a pixel is requested from an empty layer FIFO
- Transfer Error interrupt: generated when an AHB bus error occurs during data transfer

Those interrupts events are connected to the NVIC controller as described in the figure below.

Figure 85. Interrupt events

Table 91. LTDC interrupt requests

| Interrupt event | Event flag | Enable Control bit |
|-----------------|------------|--------------------|
| Line            | LIF        | LIE                |
| Register Reload | RRIF       | RRIEN              |
| FIFO Underrun   | FUDERRIF   | FUDERRIE           |
| Transfer Error  | TERRIF     | TERRIE             |

## 16.6 LTDC programming procedure

- Enable the LTDC clock in the RCC register
- Configure the required Pixel clock following the panel datasheet
- Configure the Synchronous timings: VSYNC, HSYNC, Vertical and Horizontal back porch, active data area and the front porch timings following the panel datasheet as described in the [Section 16.4.1: LTDC Global configuration parameters](#)
- Configure the synchronous signals and clock polarity in the **LTDC\_GCR** register
- If needed, configure the background color in the **LTDC\_BCCR** register
- Configure the needed interrupts in the **LTDC\_IER** and **LTDC\_LIPCR** register
- Configure the Layer1/2 parameters by programming:
  - The Layer window horizontal and vertical position in the **LTDC\_LxWHPCR** and **LTDC\_WVPCR** registers. The layer window must be in the active data area.
  - The pixel input format in the **LTDC\_LxPFCR** register
  - The color frame buffer start address in the **LTDC\_LxCFBAR** register
  - The line length and pitch of the color frame buffer in the **LTDC\_LxCFBLR** register
  - The number of lines of the color frame buffer in the **LTDC\_LxCFBLNR** register
  - if needed, load the CLUT with the RGB values and its address in the **LTDC\_LxCLUTWR** register
  - If needed, configure the default color and the blending factors respectively in the **LTDC\_LxDCCR** and **LTDC\_LxBFCR** registers
- Enable Layer1/2 and if needed the CLUT in the **LTDC\_LxCR** register
- If needed, dithering and color keying can be enabled respectively in the **LTDC\_GCR** and **LTDC\_LxCKCR** registers. It can be also enabled on the fly.
- Reload the shadow registers to active register through the **LTDC\_SRCR** register.
- Enable the LCD-TFT controller in the **LTDC\_GCR** register.
- All layer parameters can be modified on the fly except the CLUT. The new configuration has to be either reloaded immediately or during vertical blanking period by configuring the **LTDC\_SRCR** register.

*Note:* All layer's registers are shadowed. Once a register is written, it should not be modified again before the reload has been done. Thus, a new write to the same register will override the previous configuration if not yet reloaded.

## 16.7 LTDC registers

### 16.7.1 LTDC Synchronization Size Configuration Register (LTDC\_SSCR)

This register defines the number of Horizontal Synchronization pixels minus 1 and the number of Vertical Synchronization lines minus 1. Refer to [Figure 82](#) and [Section 16.4: LTDC programmable parameters](#) for an example of configuration.

Address offset: 0x08

Reset value: 0x0000 0000

|          |    |    |    |           |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|-----------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27        | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    | HSW[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15       | 14 | 13 | 12 | 11        | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | VSH[10:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:28 Reserved, must be kept at reset value

Bits 27:16 **HSW[11:0]**: Horizontal Synchronization Width (in units of pixel clock period)  
These bits define the number of Horizontal Synchronization pixel minus 1.

Bits 15:11 Reserved, must be kept at reset value

Bits 10:0 **VSH[10:0]**: Vertical Synchronization Height (in units of horizontal scan line)  
These bits define the vertical Synchronization height minus 1. It represents the number of horizontal synchronization lines.

### 16.7.2 LTDC Back Porch Configuration Register (LTDC\_BPCR)

This register defines the accumulated number of Horizontal Synchronization and back porch pixels minus 1 (**HSYNC Width + HBP - 1**) and the accumulated number of Vertical Synchronization and back porch lines minus 1 (**VSYNC Height + VBP - 1**). Refer to [Figure 82](#) and [Section 16.4: LTDC programmable parameters](#) for an example of configuration.

Address offset: 0x0C

Reset value: 0x0000 0000

|          |    |    |    |            |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|------------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27         | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    | AHBP[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15       | 14 | 13 | 12 | 11         | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | AVBP[10:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw         | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:28 Reserved, must be kept at reset value

Bits 27:16 **AHBP[11:0]**: Accumulated Horizontal back porch (in units of pixel clock period)

These bits define the Accumulated Horizontal back porch width which includes the Horizontal Synchronization and Horizontal back porch pixels minus 1.

The Horizontal back porch is the period between Horizontal Synchronization going inactive and the start of the active display part of the next scan line.

Bits 15:11 Reserved, must be kept at reset value

Bits 10:0 **AVBP[10:0]**: Accumulated Vertical back porch (in units of horizontal scan line)

These bits define the accumulated Vertical back porch width which includes the Vertical Synchronization and Vertical back porch lines minus 1.

The Vertical back porch is the number of horizontal scan lines at a start of frame to the start of the first active scan line of the next frame.

### 16.7.3 LTDC Active Width Configuration Register (LTDC\_AWCR)

This register defines the accumulated number of Horizontal Synchronization, back porch and Active pixels minus 1 (**HSYNC width + HBP + Active Width - 1**) and the accumulated number of Vertical Synchronization, back porch lines and Active lines minus 1 (**VSYNC Height + BVBP + Active Height - 1**). Refer to [Figure 82](#) and [Section 16.4: LTDC programmable parameters](#) for an example of configuration.

Address offset: 0x10

Reset value: 0x0000 0000

|          |    |    |    |           |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|-----------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27        | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    | AAW[11:0] |    |    |    |    |    |    |    |    |    |    |    |

| 15       | 14 | 13 | 12 | 11        | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | AAH[10:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:28 Reserved, must be kept at reset value

Bits 27:16 **AAW[11:0]**: Accumulated Active Width (in units of pixel clock period)

These bits define the Accumulated Active Width which includes the Horizontal Synchronization, Horizontal back porch and Active pixels minus 1.

The Active Width is the number of pixels in active display area of the panel scan line. The maximum Active Width supported is 0x400.

Bits 15:11 Reserved, must be kept at reset value

Bits 10:0 **AAH[10:0]**: Accumulated Active Height (in units of horizontal scan line)

These bits define the Accumulated Height which includes the Vertical Synchronization, Vertical back porch and the Active Height lines minus 1. The Active Height is the number of active lines in the panel. The maximum Active Height supported is 0x300.

### 16.7.4 LTDC Total Width Configuration Register (LTDC\_TWCR)

This register defines the accumulated number of Horizontal Synchronization, back porch, Active and front porch pixels minus 1 (**HSYNC Width + HBP + Active Width + HFP - 1**) and the accumulated number of Vertical Synchronization, back porch lines, Active and Front lines minus 1 (**VSYNC Height+ BVBP + Active Height + VFP - 1**). Refer to [Figure 82](#) and [Section 16.4: LTDC programmable parameters](#) for an example of configuration.

Address offset: 0x14

Reset value: 0x0000 0000

|          |    |    |    |              |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|--------------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27           | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    | TOTALW[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 16       | 14 | 13 | 12 | 11           | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

|          |    |    |    | rw           | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:28 Reserved, must be kept at reset value

Bits 27:16 **TOTALW[11:0]**: Total Width (in units of pixel clock period)

These bits defines the accumulated Total Width which includes the Horizontal Synchronization, Horizontal back porch, Active Width and Horizontal front porch pixels minus 1.

Bits 15:11 Reserved, must be kept at reset value

Bits 10:0 **TOTALH[10:0]**: Total Height (in units of horizontal scan line)

These bits defines the accumulated Height which includes the Vertical Synchronization, Vertical back porch, the Active Height and Vertical front porch Height lines minus 1.

### 16.7.5 LTDC Global Control Register (LTDC\_GCR)

This register defines the global configuration of the LCD-TFT controller.

Address offset: 0x18

Reset value: 0x0000 2220

|          |          |       |       |          |          |    |    |          |          |    |    |          |    |       |     |
|----------|----------|-------|-------|----------|----------|----|----|----------|----------|----|----|----------|----|-------|-----|

- Bit 31 **HSPOL**: Horizontal Synchronization Polarity  
This bit is set and cleared by software.  
0: Horizontal Synchronization polarity is active low  
1: Horizontal Synchronization polarity is active high
- Bit 30 **VSPOL**: Vertical Synchronization Polarity  
This bit is set and cleared by software.  
0: Vertical Synchronization is active low  
1: Vertical Synchronization is active high
- Bit 29 **DEPOL**: Data Enable Polarity  
This bit is set and cleared by software.  
0: Data Enable polarity is active low  
1: Data Enable polarity is active high
- Bit 28 **PCPOL**: Pixel Clock Polarity  
This bit is set and cleared by software.  
0: input pixel clock  
1: inverted input pixel clock
- Bits 27:17 Reserved, must be kept at reset value
- Bit 16 **DEN**: Dither Enable  
This bit is set and cleared by software.  
0: Dither disable  
1: Dither enable
- Bit 15 Reserved, must be kept at reset value
- Bits 14:12 **DRW[2:0]**: Dither Red Width  
These bits return the Dither Red Bits
- Bit 11 Reserved, must be kept at reset value
- Bits 10:8 **DGW[2:0]**: Dither Green Width  
These bits return the Dither Green Bits
- Bit 7 Reserved, must be kept at reset value
- Bits 6:4 **DBW[2:0]**: Dither Blue Width  
These bits return the Dither Blue Bits
- Bits 3:1 Reserved, must be kept at reset value
- Bit 0 **LTDCEN**: LCD-TFT controller enable bit  
This bit is set and cleared by software.  
0: LTDC disable  
1: LTDC enable

### 16.7.6 LTDC Shadow Reload Configuration Register (LTDC\_SRCR)

This register allows to reload either immediately or during the vertical blanking period, the shadow registers values to the active registers. The shadow registers are all Layer1 and Layer2 registers except the LTDC\_L1CLUTWR and the LTDC\_L2CLUTWR.

Address offset: 0x24

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |     |     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17  | 16  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |     |     |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1   | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    | VBR | IMR |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    | rw  | rw  |

Bits 31:2 Reserved, must be kept at reset value

Bit 1 **VBR**: Vertical Blanking Reload

This bit is set by software and cleared only by hardware after reload. (it cannot be cleared through register write once it is set)

0: No effect

1: The shadow registers are reloaded during the vertical blanking period (at the beginning of the first line after the Active Display Area)

Bit 0 **IMR**: Immediate Reload

This bit is set by software and cleared only by hardware after reload.

0: No effect

1: The shadow registers are reloaded immediately

**Note:** The shadow registers read back the active values. Until the reload has been done, the 'old' value will be read.

### 16.7.7 LTDC Background Color Configuration Register (LTDC\_BCCR)

This register defines the background color (RGB888).

Address offset: 0x2C

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |

Bits 31:24 Reserved, must be kept at reset value

Bits 23:16 **BCRED[7:0]**: Background Color Red value  
These bits configure the background red value

Bits 15:8 **BCGREEN[7:0]**: Background Color Green value  
These bits configure the background green value

Bits 7:0 **BCBLUE[7:0]**: Background Color Blue value  
These bits configure the background blue value

### 16.7.8 LTDC Interrupt Enable Register (LTDC\_IER)

This register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

Address offset: 0x34

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |      |        |      |     |
|----------|----|----|----|----|----|----|----|----|----|----|----|------|--------|------|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19   | 18     | 17   | 16  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |      |        |      |     |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3    | 2      | 1    | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    | RRIE | TERRIE | FUIE | LIE |
|          |    |    |    |    |    |    |    |    |    |    |    | rw   | rw     | rw   | rw  |

Bits 31:4 Reserved, must be kept at reset value

Bit 3 **RRIE**: Register Reload interrupt enable  
This bit is set and cleared by software  
0: Register Reload interrupt disable  
1: Register Reload interrupt enable

Bit 2 **TERRIE**: Transfer Error Interrupt Enable  
This bit is set and cleared by software  
0: Transfer Error interrupt disable  
1: Transfer Error interrupt enable

Bit 1 **FUIE**: FIFO Underrun Interrupt Enable  
This bit is set and cleared by software  
0: FIFO Underrun interrupt disable  
1: FIFO Underrun Interrupt enable

Bit 0 **LIE**: Line Interrupt Enable  
This bit is set and cleared by software  
0: Line interrupt disable  
1: Line Interrupt enable

### 16.7.9 LTDC Interrupt Status Register (LTDC\_ISR)

This register returns the interrupt status flag

Address offset: 0x38

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |      |        |      |     |
|----------|----|----|----|----|----|----|----|----|----|----|----|------|--------|------|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19   | 18     | 17   | 16  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |      |        |      |     |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3    | 2      | 1    | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    | RRIF | TERRIF | FUIF | LIF |
|          |    |    |    |    |    |    |    |    |    |    |    | r    | r      | r    | r   |

Bits 31:24 Reserved, must be kept at reset value

Bit 3 **RRIF**: Register Reload Interrupt Flag

0: No Register Reload interrupt generated

1: Register Reload interrupt generated when a vertical blanking reload occurs (and the first line after the active area is reached)

Bit 2 **TERRIF**: Transfer Error interrupt flag

0: No Transfer Error interrupt generated

1: Transfer Error interrupt generated when a Bus error occurs

Bit 1 **FUIF**: FIFO Underrun Interrupt flag

0: NO FIFO Underrun interrupt generated.

1: A FIFO underrun interrupt is generated, if one of the layer FIFOs is empty and pixel data is read from the FIFO

Bit 0 **LIF**: Line Interrupt flag

0: No Line interrupt generated

1: A Line interrupt is generated, when a programmed line is reached

### 16.7.10 LTDC Interrupt Clear Register (LTDC\_ICR)

Address offset: 0x3C

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |       |         |       |      |
|----------|----|----|----|----|----|----|----|----|----|----|----|-------|---------|-------|------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19    | 18      | 17    | 16   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |       |         |       |      |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3     | 2       | 1     | 0    |
| Reserved |    |    |    |    |    |    |    |    |    |    |    | CRRIF | CTERRIF | CFUIF | CLIF |
|          |    |    |    |    |    |    |    |    |    |    |    | w     | w       | w     | w    |

Bits 31:24 Reserved, must be kept at reset value

Bit 3 **CRRIF**: Clears Register Reload Interrupt Flag

0: No effect

1: Clears the RRIF flag in the LTDC\_ISR register

Bit 2 **CTERRIF**: Clears the Transfer Error Interrupt Flag

0: No effect

1: Clears the TERRIF flag in the LTDC\_ISR register.

Bit 1 **CFUIF**: Clears the FIFO Underrun Interrupt flag

0: No effect

1: Clears the FUDERRIF flag in the LTDC\_ISR register.

Bit 0 **CLIF**: Clears the Line Interrupt Flag

0: No effect

1: Clears the LIF flag in the LTDC\_ISR register.

### 16.7.11 LTDC Line Interrupt Position Configuration Register (LTDC\_LIPCR)

This register defines the position of the line interrupt. The line value to be programmed depends on the timings parameters. Refer to [Figure 82](#).

Address offset: 0x40

Reset value: 0x0000 0000

|          |    |    |    |    |             |     |     |     |     |     |     |     |     |     |     |
|----------|----|----|----|----|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31       | 30 | 29 | 28 | 27 | 26          | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| Reserved |    |    |    |    |             |     |     |     |     |     |     |     |     |     |     |
| 15       | 14 | 13 | 12 | 11 | 10          | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| Reserved |    |    |    |    | LIPOS[10:0] |     |     |     |     |     |     |     |     |     |     |
|          |    |    |    |    | r/w         | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:11 Reserved, must be kept at reset value

Bits 10:0 **LIPOS[10:0]**: Line Interrupt Position

These bits configure the line interrupt position

### 16.7.12 LTDC Current Position Status Register (LTDC\_CPSR)

Address offset: 0x44

Reset value: 0x0000 0000

|             |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31          | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CXPOS[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15          | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CYPOS[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r           | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:16: **CXPOS[15:0]**: Current X Position  
These bits return the current X position

Bits 15:0 **CYPOS[15:0]**: Current Y Position  
These bits return the current Y position

### 16.7.13 LTDC Current Display Status Register (LTDC\_CDSR)

This register returns the status of the current display phase which is controlled by the HSYNC, VSYNC, and Horizontal/Vertical DE signals.

Example: if the current display phase is the vertical synchronization, the VSYNC S bit is set (active high). If the current display phase is the horizontal synchronization, the HSYNC S bit is active high.

Address offset: 0x48

Reset value: 0x0000 000F

|          |    |    |    |    |    |    |    |    |    |    |    |            |            |      |      |
|----------|----|----|----|----|----|----|----|----|----|----|----|------------|------------|------|------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19         | 18         | 17   | 16   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |            |            |      |      |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3          | 2          | 1    | 0    |
| Reserved |    |    |    |    |    |    |    |    |    |    |    | HSYNC<br>S | VSYNC<br>S | HDES | VDES |
|          |    |    |    |    |    |    |    |    |    |    |    | r          | r          | r    | r    |

Bits 31:24 Reserved, must be kept at reset value

Bit 3 **HSYNC S**: Horizontal Synchronization display Status

0: Active low

1: Active high

Bit 2 **VSYNC S**: Vertical Synchronization display Status

0: Active low

1: Active high

Bit 1 **HDES**: Horizontal Data Enable display Status

0: Active low

1: Active high

Bit 0 **VDES**: Vertical Data Enable display Status

0: Active low

1: Active high

**Note:** The returned status does not depend on the configured polarity in the **LTDC\_GCR** register, instead it returns the current active display phase.

### 16.7.14 LTDC Layerx Control Register (LTDC\_LxCR) (where x=1..2)

Address offset:  $0x84 + 0x80 \times (Layerx - 1)$ ,  $Layerx = 1$  or  $2$

Reset value:  $0x0000\ 0000$

|          |    |    |    |    |    |    |    |    |    |    |        |          |    |        |     |
|----------|----|----|----|----|----|----|----|----|----|----|--------|----------|----|--------|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20     | 19       | 18 | 17     | 16  |
| Reserved |    |    |    |    |    |    |    |    |    |    |        |          |    |        |     |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4      | 3        | 2  | 1      | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    | CLUTEN | Reserved |    | COLKEN | LEN |
|          |    |    |    |    |    |    |    |    |    |    | rw     |          |    | rw     | rw  |

Bits 31:5 Reserved, must be kept at reset value

Bit 4 **CLUTEN**: Color Look-Up Table Enable

This bit is set and cleared by software.

0: Color Look-Up Table disable

1: Color Look-Up Table enable

The CLUT is only meaningful for L8, AL44 and AL88 pixel format. Refer to [Color Look-Up Table \(CLUT\) on page 488](#)

Bit 3 Reserved, must be kept at reset value

Bit 2 Reserved, must be kept at reset value

Bit 1 **COLKEN**: Color Keying Enable

This bit is set and cleared by software.

0: Color Keying disable

1: Color Keying enable

Bit 0 **LEN**: Layer Enable

This bit is set and cleared by software.

0: Layer disable

1: Layer enable

### 16.7.15 LTDC Layerx Window Horizontal Position Configuration Register (LTDC\_LxWHPCR) (where x=1..2)

This register defines the Horizontal Position (first and last pixel) of the layer 1 or 2 window.

The first visible pixel of a line is the programmed value of **AHBP[10:0] bits + 1** in the **LTDC\_BPCR** register.

The last visible pixel of a line is the programmed value of **AAW[10:0] bits** in the **LTDC\_AWCR** register.

Address offset:  $0x88 + 0x80 \times (\text{Layerx} - 1)$ ,  $\text{Layerx} = 1 \text{ or } 2$

Reset value: **0x0000 0000**

|          |    |    |    |               |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|---------------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27            | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    | WHSPPOS[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15       | 14 | 13 | 12 | 11            | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    | WHSTPOS[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    | rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:28 Reserved, must be kept at reset value

Bits 27:16 **WHSPPOS[11:0]**: Window Horizontal Stop Position

These bits configure the last visible pixel of a line of the layer window.

The following condition must be respected:

$\text{WHSPPOS}[11:0] \geq \text{AHBP}[10:0] \text{ bits} + 1$  (programmed in LTDC\_BPCR register)

Bits 15:12 Reserved, must be kept at reset value

Bits 11:0 **WHSTPOS[11:0]**: Window Horizontal Start Position

These bits configure the first visible pixel of a line of the layer window.

The following condition must be respected:

$\text{WHSTPOS}[11:0] \text{ must be } \leq \text{AAW}[10:0] \text{ bits}$  (programmed in the LTDC\_AWCR register).

Example:

The LTDC\_BPCR register is configured to 0x000E0005(AHBP[11:0] is 0xE) and the LTDC\_AWCR register is configured to 0x028E01E5(AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the Active data area.

1. Layer window first pixel: WHSTPOS[11:0] should be programmed to 0x14 (0xE+1+0x5)
2. Layer window last pixel: WHSPPOS[11:0] should be programmed to 0x28A

### 16.7.16 LTDC Layerx Window Vertical Position Configuration Register (LTDC\_LxWVPCR) (where x=1..2)

This register defines the vertical position (first and last line) of the layer1 or 2 window.

The first visible line of a frame is the programmed value of **AVBP[10:0] bits + 1** in the register **LTDC\_BPCR** register.

The last visible line of a frame is the programmed value of **AAH[10:0] bits** in the **LTDC\_AWCR** register.

Address offset:  $0x8C + 0x80 \times (\text{Layerx} - 1)$ , *Layerx* = 1 or 2

Reset value: *0x0000 0000*

|          |    |    |    |    |               |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----|---------------|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26            | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    | WVSPPOS[10:0] |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    |    | rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15       | 14 | 13 | 12 | 11 | 10            | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    | WVSTPOS[10:0] |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    |    | rw            | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:27 Reserved, must be kept at reset value

Bits 26:16 **WVSPPOS[10:0]**: Window Vertical Stop Position

These bits configures the last visible line of the layer window.

The following condition must be respected:

WVSPPOS[11:0] must be  $\geq$  AVBP[10:0] bits + 1 (programmed in LTDC\_BPCR register)

Bits 15:11 Reserved, must be kept at reset value

Bits 10:0 **WVSTPOS[10:0]**: Window Vertical Start Position

These bits configure the first visible line of the layer window.

The following condition must be respected:

WVSTPOS[11:0] must be  $\leq$  AAH[10:0] bits (programmed in the LTDC\_AWCR register)

Example:

The LTDC\_BPCR register is configured to 0x000E0005 (AVBP[10:0] is 0x5) and the LTDC\_AWCR register is configured to 0x028E01E5 (AAH[10:0] is 0x1E5). To configure the vertical position of a window size of 630x460, with vertical start offset of 8 lines in the Active data area:

1. Layer window first line: WVSTPOS[10:0] should be programmed to 0xE ( $0x5 + 1 + 0x8$ )
2. Layer window last line: WVSPPOS[10:0] should be programmed to 0x1DA

### 16.7.17 LTDC Layerx Color Keying Configuration Register (LTDC\_LxCKCR) (where x=1..2)

This register defines the color key value (RGB), which is used by the Color Keying.

Address offset:  $0x90 + 0x80 \times (Layerx - 1)$ ,  $Layerx = 1$  or  $2$

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved     |    |    |    |    |    |    |    | CKRED[7:0]  |    |    |    |    |    |    |    |
|              |    |    |    |    |    |    |    | rw          | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CKGREEN[7:0] |    |    |    |    |    |    |    | CKBLUE[7:0] |    |    |    |    |    |    |    |
| rw           |    |    |    |    |    |    |    | rw          | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 Reserved, must be kept at reset value

Bits 23:16 **CKRED[7:0]**: Color Key Red value

Bits 15:8 **CKGREEN[7:0]**: Color Key Green value

Bits 7:0 **CKBLUE[7:0]**: Color Key Blue value

### 16.7.18 LTDC Layerx Pixel Format Configuration Register (LTDC\_LxPFCR) (where x=1..2)

This register defines the pixel format which is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB).

Address offset:  $0x94 + 0x80 \times (Layerx - 1)$ ,  $Layerx = 1$  or  $2$

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |         |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|---------|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19      | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |         |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3       | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    | PF[2:0] |    |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    | rw      | rw | rw |    |

Bits 31:3 Reserved, must be kept at reset value

Bits 2:0 **PF[2:0]**: Pixel Format

These bits configures the Pixel format

000: ARGB8888

001: RGB888

010: RGB565

011: ARGB1555

100: ARGB4444

101: L8 (8-Bit Luminance)

110: AL44 (4-Bit Alpha, 4-Bit Luminance)

111: AL88 (8-Bit Alpha, 8-Bit Luminance)

### 16.7.19 LTDC Layerx Constant Alpha Configuration Register (LTDC\_LxCACR) (where x=1..2)

This register defines the constant alpha value (divided by 255 by Hardware), which is used in the alpha blending. Refer to LTDC\_LxBFCR register.

Address offset:  $0x98 + 0x80 \times (Layerx - 1)$ ,  $Layerx = 1$  or  $2$

Reset value:  $(Layerx - 1) 0x0000\ 00FF$

|          |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    | CONSTA[7:0] |    |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    | rw          | rw | rw | rw | rw | rw | rw | rw |

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **CONSTA[7:0]**: Constant Alpha

These bits configure the Constant Alpha used for blending. The Constant Alpha is divided by 255 by hardware.

Example: if the programmed Constant Alpha is 0xFF, the Constant Alpha value is  $255/255=1$

### 16.7.20 LTDC Layerx Default Color Configuration Register (LTDC\_LxDCCR) (where x=1..2)

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

Address offset:  $0x9C + 0x80 \times (Layerx - 1)$ ,  $Layerx = 1$  or  $2$

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |             |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23          | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DCALPHA[7:0] |    |    |    |    |    |    |    | DCRED[7:0]  |    |    |    |    |    |    |    |
| rw           |    |    |    |    |    |    |    | rw          | rw | rw | rw | rw | rw | rw | rw |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7           | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DCGREEN[7:0] |    |    |    |    |    |    |    | DCBLUE[7:0] |    |    |    |    |    |    |    |
| rw           |    |    |    |    |    |    |    | rw          | rw | rw | rw | rw | rw | rw | rw |

- Bits 31:24 **DCALPHA[7:0]**: Default Color Alpha  
These bits configure the default alpha value
- Bits 23:16 **DCRED[7:0]**: Default Color Red  
These bits configure the default red value
- Bits 15:8 **DCGREEN[7:0]**: Default Color Green  
These bits configure the default green value
- Bits 7:0 **DCBLUE[7:0]**: Default Color Blue  
These bits configure the default blue value

### 16.7.21 LTDC Layerx Blending Factors Configuration Register (LTDC\_LxBFCR) (where x=1..2)

This register defines the blending factors F1 and F2.

The general blending formula is:  $BC = BF1 \times C + BF2 \times Cs$

- BC = Blended color
- BF1 = Blend Factor 1
- C = Current layer color
- BF2 = Blend Factor 2
- Cs = subjacent layers blended color

Address offset:  $0xA0 + 0x80 \times (Layerx - 1)$ ,  $Layerx = 1$  or  $2$

Reset value: 0x0000 0607

|          |    |    |    |    |          |    |    |          |    |    |    |    |          |    |    |
|----------|----|----|----|----|----------|----|----|----------|----|----|----|----|----------|----|----|
| 31       | 30 | 29 | 28 | 27 | 26       | 25 | 24 | 23       | 22 | 21 | 20 | 19 | 18       | 17 | 16 |
| Reserved |    |    |    |    |          |    |    |          |    |    |    |    |          |    |    |
| 15       | 14 | 13 | 12 | 11 | 10       | 9  | 8  | 7        | 6  | 5  | 4  | 3  | 2        | 1  | 0  |
| Reserved |    |    |    |    | BF1[2:0] |    |    | Reserved |    |    |    |    | BF2[2:0] |    |    |
|          |    |    |    |    | rw       | rw | rw |          |    |    |    |    | rw       | rw | rw |

Bits 31:11 Reserved, must be kept at reset value

Bits 10:8 **BF1[2:0]**: Blending Factor 1

These bits select the blending factor F1

000: Reserved

001: Reserved

010: Reserved

011: Reserved

100: Constant Alpha

101: Reserved

110: Pixel Alpha x Constant Alpha

111: Reserved

Bits 7:3 Reserved, must be kept at reset value

Bits 2:0 **BF2[2:0]**: Blending Factor 2

These bits select the blending factor F2

000: Reserved

001: Reserved

010: Reserved

011: Reserved

100: Reserved

101: 1 - Constant Alpha

110: Reserved

111: 1 - (Pixel Alpha x Constant Alpha)

**Note:** The Constant Alpha value, is the programmed value in the LxCACR register divided by 255 by hardware.

*Example: Only layer1 is enabled, BF1 configured to Constant Alpha*

*BF2 configured to 1 - Constant Alpha*

*Constant Alpha: The Constant Alpha programmed in the LxCACR register is 240 (0xF0). Thus, the Constant Alpha value is  $240/255 = 0.94$*

*C: Current Layer Color is 128*

*Cs: Background color is 48*

*Layer1 is blended with the background color.*

*$BC = \text{Constant Alpha} \times C + (1 - \text{Constant Alpha}) \times Cs = 0.94 \times 128 + (1 - 0.94) \times 48 = 123$ .*

### 16.7.22 LTDC Layerx Color Frame Buffer Address Register (LTDC\_LxCFBAR) (where x=1..2)

This register defines the color frame buffer start address which has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer.

Address offset:  $0xAC + 0x80 \times (\text{Layerx} - 1)$ , Layerx = 1 or 2

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CFBADD[31:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW           | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CFBADD[31:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW           | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:0 **CFBADD[31:0]**: Color Frame Buffer Start Address

These bits defines the color frame buffer start address.

### 16.7.23 LTDC Layerx Color Frame Buffer Length Register (LTDC\_LxCFBLR) (where x=1..2)

This register defines the color frame buffer line length and pitch.

Address offset:  $0xB0 + 0x80 \times (\text{Layerx} - 1)$ , Layerx = 1 or 2

Reset value: 0x0000 0000

|          |    |    |             |    |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|-------------|----|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28          | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    | CFBP[12:0]  |    |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    | rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15       | 14 | 13 | 12          | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    | CFBLL[12:0] |    |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    | rW          | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:29 Reserved, must be kept at reset value

Bits 28:16 **CFBP[12:0]**: Color Frame Buffer Pitch in bytes

These bits define the pitch which is the increment from the start of one line of pixels to the start of the next line in bytes.

Bits 15:13 Reserved, must be kept at reset value

Bits 12:0 **CFBLL[12:0]**: Color Frame Buffer Line Length

These bits define the length of one line of pixels in bytes + 3.

The line length is computed as follows: Active high width x number of bytes per pixel + 3.

Example:

- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is  $256 \times 2 = 512$  bytes), where pitch = line length requires a value of 0x02000203 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is  $320 \times 3 = 960$ ), where pitch = line length requires a value of 0x03C003C3 to be written into this register.

#### 16.7.24 LTDC Layerx ColorFrame Buffer Line Number Register (LTDC\_LxCFBLNR) (where x=1..2)

This register defines the number of lines in the color frame buffer.

Address offset:  $0xB4 + 0x80 \times (\text{Layerx} - 1)$ , Layerx = 1 or 2

Reset value: 0x0000 0000

|          |    |    |    |    |               |     |     |     |     |     |     |     |     |     |     |
|----------|----|----|----|----|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31       | 30 | 29 | 28 | 27 | 26            | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
| Reserved |    |    |    |    |               |     |     |     |     |     |     |     |     |     |     |
| 15       | 14 | 13 | 12 | 11 | 10            | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| Reserved |    |    |    |    | CFBLNBR[10:0] |     |     |     |     |     |     |     |     |     |     |
|          |    |    |    |    | r/w           | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 31:11 Reserved, must be kept at reset value

Bits 10:0 **CFBLNBR[10:0]**: Frame Buffer Line Number

These bits define the number of lines in the frame buffer which corresponds to the Active high width.

**Note:** The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt will be generated if enabled.

The start address and pitch settings on the other hand define the correct start of every line in memory.

### 16.7.25 LTDC Layerx CLUT Write Register (LTDC\_LxCLUTWR) (where x=1..2)

This register defines the CLUT address and the RGB value.

Address offset:  $0xC4 + 0x80 \times (Layerx - 1)$ ,  $Layerx = 1$  or  $2$

Reset value: 0x0000 0000

|              |    |    |    |    |    |    |    |           |    |    |    |    |    |    |    |
|--------------|----|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|
| 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23        | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CLUTADD[7:0] |    |    |    |    |    |    |    | RED[7:0]  |    |    |    |    |    |    |    |
| w            | w  | w  | w  | w  | w  | w  | w  | w         | w  | w  | w  | w  | w  | w  | w  |
| 15           | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7         | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| GREEN[7:0]   |    |    |    |    |    |    |    | BLUE[7:0] |    |    |    |    |    |    |    |
| w            | w  | w  | w  | w  | w  | w  | w  | w         | w  | w  | w  | w  | w  | w  | w  |

Bits 31:24 **CLUTADD[7:0]**: CLUT Address

These bits configure the CLUT address (color position within the CLUT) of each RGB value

Bits 23:16 **RED[7:0]**: Red value

These bits configure the red value

Bits 15:8 **GREEN[7:0]**: Green value

These bits configure the green value

Bits 7:0 **BLUE[7:0]**: Blue value

These bits configure the blue value

**Note:** *The CLUT write register should only be configured during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the **LTDC\_LxCR** register.*

*The CLUT is only meaningful for L8, AL44 and AL88 pixel format.*

## 16.7.26 LTDC register map

The following table summarizes the LTDC registers. Refer to the register boundary addresses table for the LTDC register base address.

**Table 92. LTDC register map and reset values**

| Offset | Register     | 31          | 30    | 29    | 28    | 27      | 26            | 25 | 24 | 23 | 22       | 21 | 20 | 19 | 18 | 17       | 16          | 15       | 14 | 13 | 12            | 11       | 10 | 9 | 8        | 7        | 6 | 5 | 4        | 3      | 2      | 1        | 0 |

## 17 Advanced-control timers (TIM1 and TIM8)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 17.1 TIM1 and TIM8 introduction

The advanced-control timers (TIM1 and TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1 and TIM8) and general-purpose (TIMx) timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 17.3.20](#).

## 17.2 TIM1 and TIM8 main features

TIM1 and TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- Break input to put the timer’s output signals in reset state or in a known state.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

**Figure 86. Advanced-control timer block diagram**

## 17.3 TIM1 and TIM8 functional description

### 17.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC)
- Auto-reload register (TIMx\_ARR)
- Repetition counter register (TIMx\_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx\_CR1 register.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 87* and *Figure 88* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 87. Counter timing diagram with prescaler division change from 1 to 2

Figure 88. Counter timing diagram with prescaler division change from 1 to 4

## 17.3.2 Counter modes

### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register plus one (TIMx\_RCR+1). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 93. Counter timing diagram, update event when ARPE=0 (TIMx\_ARR not preloaded)

Figure 94. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)

### Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx\_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register plus one (TIMx\_RCR+1). Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

Figure 97. Counter timing diagram, internal clock divided by 4

Figure 98. Counter timing diagram, internal clock divided by N

**Figure 99. Counter timing diagram, update event when repetition counter is not used**

### Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx\_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx\_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 100. Counter timing diagram, internal clock divided by 1, TIMx\_ARR = 0x6**

1. Here, center-aligned mode 1 is used (for more details refer to [Section 17.4: TIM1 and TIM8 registers](#)).

### 17.3.3 Repetition counter

[Section 17.3.1: Time-base unit](#) describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx\_ARR auto-reload register, TIMx\_PSC prescaler register, but also TIMx\_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx\_RCR repetition counter register.

The repetition counter is decremented:

- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.  
Although this limits the maximum number of repetition to 128 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is  $2 \times T_{ck}$ , due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx\_RCR register value (refer to [Figure 106](#)). When the update event is generated by software (by setting the UG bit in TIMx\_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx\_RCR register.

In center-aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was started. If the RCR was written before starting the counter, the UEV occurs on the overflow. If the RCR was written after starting the counter, the UEV occurs on the underflow. For example for RCR = 3, the UEV is generated on each 4th overflow or underflow event depending on when RCR was written.

**Figure 106. Update rate examples depending on mode and TIMx\_RCR register settings**

### 17.3.4 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1: external input pin
- External clock mode2: external trigger input ETR
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, the user can configure Timer 1 to act as a prescaler for Timer 2. Refer to [Using one timer as prescaler for another timer](#) for more details.

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 107](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 107. Control circuit in normal mode, internal clock divided by 1**

#### External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 108. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the trigger input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

**Note:** The capture prescaler is not used for triggering, so the user does not need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

Figure 109. Control circuit in external clock mode 1

External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on the external trigger input ETR. [Figure 110](#) gives an overview of the external trigger input block.

Figure 110. External trigger input block

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write  $ETF[3:0]=0000$  in the TIMx\_SMCR register.
2. Set the prescaler by writing  $ETPS[1:0]=01$  in the TIMx\_SMCR register
3. Select rising edge detection on the ETR pin by writing  $ETP=0$  in the TIMx\_SMCR register
4. Enable external clock mode 2 by writing  $ECE=1$  in the TIMx\_SMCR register.
5. Enable the counter by writing  $CEN=1$  in the TIMx\_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

**Figure 111. Control circuit in external clock mode 2**

### 17.3.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

[Figure 112](#) to [Figure 115](#) give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 112. Capture/compare channel (example: channel 1 input stage)

The output stage generates an intermediate waveform that is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 113. Capture/compare channel 1 main circuit

Figure 114. Output stage of capture/compare channel (channel 1 to 3)

MS35909V1

Figure 115. Output stage of capture/compare channel (channel 4)

MS37370V1

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 17.3.6 Input capture mode

In Input capture mode, the Capture/Compare registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx\_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when written to '0'.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx\_CCR1 register becomes read-only.
- Program the needed input filter duration with respect to the signal connected to the timer (by programming ICxF bits in the TIMx\_CCMRx register if the input is a TIx input). Let's imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.
- Select the edge of the active transition on the TI1 channel by writing CC1P and CC1NP bits to 0 in the TIMx\_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx\_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 17.3.7 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, user can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

- Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P and CC1NP bits to '0' (active on rising edge).
- Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P and CC2NP bits to '1' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

**Figure 116. PWM input mode timing**

### 17.3.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, the user just needs to write 101 in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus OCXREF is

forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 17.3.9 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx\_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register for the DMA request selection).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
  - Write OCxM = 011 to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = 0 to disable preload register
  - Write CCxP = 0 to select active high polarity
  - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 117](#).

**Figure 117. Output compare mode, toggle on OC1.**

### 17.3.10 PWM mode

Pulse Width Modulation mode allows generating a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing '110' (PWM mode 1) or '111' (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, the user must initialize all the registers by setting the UG bit in the TIMx\_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx\_CCER and TIMx\_BDTR registers). Refer to the TIMx\_CCER register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

#### PWM edge-aligned mode

- Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low. Refer to [Upcounting mode](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the

compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxRef is held at '0'.

Figure 118 shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

**Figure 118. Edge-aligned PWM waveforms (ARR=8)**

- **Downcounting configuration**

Downcounting is active when DIR bit in TIMx\_CR1 register is high. Refer to [Downcounting mode](#)

In PWM mode 1, the reference signal OCxRef is low as long as TIMx\_CNT > TIMx\_CCRx else it becomes high. If the compare value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, then OCxREF is held at '1'. 0% PWM is not possible in this mode.

### **PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are different from '00' (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the

TIMx\_CR1 register is updated by hardware and must not be changed by software. Refer to [Center-aligned mode \(up/down counting\)](#).

Figure 119 shows some center-aligned PWM waveforms in an example where:

- TIMx\_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx\_CR1 register.

**Figure 119. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

- in the TIMx\_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
    - The direction is not updated if the user writes a value in the counter greater than the auto-reload value (TIMx\_CNT > TIMx\_ARR). For example, if the counter was counting up, it will continue to count up.
    - The direction is updated if the user writes 0 or write the TIMx\_ARR value in the counter but no Update Event UEV is generated.
  - The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### 17.3.11 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1 and TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

User can select the polarity of the outputs (main output OCx or complementary OCxN) independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx\_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx\_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx\_BDTR and TIMx\_CR2 registers. Refer to [Table 95](#) for more details. In particular, the dead-time is activated when switching to the IDLE state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. DTG[7:0] bits of the TIMx\_BDTR register are used to control the dead-time generation for all channels. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 120. Complementary output with dead-time insertion.****Figure 121. Dead-time waveforms with delay greater than the negative pulse.****Figure 122. Dead-time waveforms with delay greater than the positive pulse.**

The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx\_BDTR register. Refer to [Section 17.4.18: TIM1 and TIM8 break and dead-time register \(TIMx\\_BDTR\)](#) for delay calculation.

### Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx\_CCER register.

This allows the user to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other possibilities are to

have both outputs at inactive level or both outputs active and complementary with dead-time.

*Note:* When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

### 17.3.12 Using the break function

When using the break function, the output enable signals and inactive levels are modified according to additional control bits (MOE, OSSI and OSSR bits in the TIMx\_BDTR register, OISx and OISxN bits in the TIMx\_CR2 register). In any case, the OCx and OCxN outputs cannot be set both to active level at a given time. Refer to [Table 95](#) for more details.

The break source can be either the break input pin or a clock failure event, generated by the Clock Security System (CSS), from the Reset Clock Controller. For further information on the Clock Security System, refer to [Section 7.2.7: Clock security system \(CSS\)](#).

When exiting from reset, the break circuit is disabled and the MOE bit is low. User can enable the break function by setting the BKE bit in the TIMx\_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx\_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is written to 1 whereas it was low, a delay (dummy instruction) must be inserted before reading it correctly. This is because the user writes an asynchronous signal, but reads a synchronous signal.

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or in reset state (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx\_CR2 register as soon as MOE=0. If OSSI=0 then the timer releases the enable output else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their

active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2  $ck_{tim}$  clock cycles).

- If OSS1=0 then the timer releases the enable outputs else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx\_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx\_DIER register is set. A DMA request can be sent if the BDE bit in the TIMx\_DIER register is set.
- If the AOE bit in the TIMx\_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written to '1' again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

**Note:** *The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.*

The break can be generated by the BRK input which has a programmable polarity and an enable bit BKE in the TIMx\_BDTR register.

There are two solutions to generate a break:

- By using the BRK input which has a programmable polarity and an enable bit BKE in the TIMx\_BDTR register
- By software through the BG bit of the TIMx\_EGR register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows freezing the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The user can choose from three levels of protection selected by the LOCK bits in the TIMx\_BDTR register. Refer to [Section 17.4.18: TIM1 and TIM8 break and dead-time register \(TIMx\\_BDTR\)](#). The LOCK bits can be written only once after an MCU reset.

Figure 123 shows an example of behavior of the outputs in response to a break.

Figure 123. Output behavior in response to a break.

### 17.3.13 Clearing the OCxREF signal on an external event

The OCxREF signal for a given channel can be driven Low by applying a High level to the ETRF input (OCxCE enable bit of the corresponding TIMx\_CCMRx register set to '1'). The OCxREF signal remains Low until the next update event, UEV, occurs.

This function can only be used in output compare and PWM modes, and does not work in forced mode.

For example, the ETR signal can be connected to the output of a comparator to be used for current handling. In this case, the ETR must be configured as follow:

1. The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx\_SMCR register set to '00'.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx\_SMCR register set to '0'.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

Figure 124 shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

**Figure 124. Clearing TIMx OCxREF**

**Note:** In case of a PWM with a 100% duty cycle (if  $CCR_x > ARR$ ), then OCxREF is enabled again at the next counter overflow.

### 17.3.14 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. The user can thus program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx\_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx\_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx\_DIER register) or a DMA request (if the COMDE bit is set in the TIMx\_DIER register).

*Figure 125* describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

**Figure 125. 6-step generation, COM example (OSSR=1)**

### 17.3.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. Select One-pulse mode by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting:  $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ )
- In downcounting:  $CNT > CCRx$

**Figure 126. Example of one pulse mode.**

For example the user may want to generate a positive pulse on OC1 with a length of t<sub>PULSE</sub> and after a delay of t<sub>DELAY</sub> as soon as a positive edge is detected on the TI2 input pin.

Let's use TI2FP2 as trigger 1:

- Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx\_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx\_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='110' in the TIMx\_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let us say the user wants to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this, enable PWM mode 2 by writing OC1M=111 in the TIMx\_CCMR1 register. The user can optionally enable the preload registers by writing OC1PE='1' in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case the compare value must be written in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

The user only wants one pulse (Single mode), so '1' must be written in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive Mode is selected.

Particular case: OCx fast enable:

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY min}}$  we can get.

If the user wants to output a waveform with the minimum delay, the OCxFE bit in the TIMx\_CCMRx register must be set. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 17.3.16 Encoder interface mode

To select Encoder Interface mode write SMS='001' in the TIMx\_SMCR register if the counter is counting on TI2 edges only, SMS='010' if it is counting on TI1 edges only and SMS='011' if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx\_CCER register. When needed, the user can program the input filter as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to [Table 93](#). The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx\_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx\_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the

TIMx\_ARR register (0 to ARR or ARR down to 0 depending on the direction). So user must configure TIMx\_ARR before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the incremental encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor.

[Table 93](#) summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

**Table 93. Counting direction versus encoder signals**

| Active edge             | Level on opposite signal<br>(TI1FP1 for TI2, TI2FP2 for TI1) | TI1FP1 signal |          | TI2FP2 signal |          |
|-------------------------|--------------------------------------------------------------|---------------|----------|---------------|----------|
|                         |                                                              | Rising        | Falling  | Rising        | Falling  |
| Counting on TI1 only    | High                                                         | Down          | Up       | No Count      | No Count |
|                         | Low                                                          | Up            | Down     | No Count      | No Count |
| Counting on TI2 only    | High                                                         | No Count      | No Count | Up            | Down     |
|                         | Low                                                          | No Count      | No Count | Down          | Up       |
| Counting on TI1 and TI2 | High                                                         | Down          | Up       | Up            | Down     |
|                         | Low                                                          | Up            | Down     | Down          | Up       |

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

[Figure 127](#) gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx\_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S='01' (TIMx\_CCMR2 register, TI1FP2 mapped on TI2).
- CC1P='0', CC1NP='0', and IC1F = '0000' (TIMx\_CCER register, TI1FP1 non-inverted, TI1FP1=TI1).
- CC2P='0', CC2NP='0', and IC2F = '0000' (TIMx\_CCER register, TI1FP2 non-inverted, TI1FP2= TI2).
- SMS='011' (TIMx\_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx\_CR1 register, Counter enabled).

**Figure 127. Example of counter operation in encoder interface mode.**

Figure 128 gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P='1').

**Figure 128. Example of encoder interface mode with TI1FP1 polarity inverted.**

The timer, when configured in Encoder Interface mode provides information on the sensor's current position. The user can obtain dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request generated by a real-time clock.

### 17.3.17 Timer input XOR function

The TI1S bit in the TIMx\_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx\_CH1, TIMx\_CH2 and TIMx\_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. An example of this feature used to interface Hall sensors is given in [Section 17.3.18](#).

### 17.3.18 Interfacing with Hall sensors

This is done using the advanced-control timers (TIM1 or TIM8) to generate PWM signals to drive the motor and another timer TIMx (TIM2, TIM3, TIM4 or TIM5) referred to as “interfacing timer” in [Figure 129](#). The “interfacing timer” captures the 3 timer input pins (TIMx\_CH1, TIMx\_CH2, and TIMx\_CH3) connected through a XOR to the TI1 input channel (selected by setting the TI1S bit in the TIMx\_CR2 register).

The slave mode controller is configured in reset mode; the slave input is TI1F\_ED. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TRC (see [Figure 112](#)). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (TIM1 or TIM8) (by triggering a COM event). The TIM1 timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer (TIM1 or TIM8) through the TRGO output.

Example: the user wants to change the PWM configuration of the advanced-control timer TIM1 after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the TI1 input channel by writing the TI1S bit in the TIMx\_CR2 register to ‘1’,
- Program the time base: write the TIMx\_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program channel 1 in capture mode (TRC selected): write the CC1S bits in the TIMx\_CCMR1 register to ‘11’. The user can also program the digital filter if needed,
- Program channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx\_CCMR1 register,
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx\_CR2 register to ‘101’,

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx\_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx\_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of OC2REF).

Figure 129 describes this example.

Figure 129. Example of Hall sensor interface

### 17.3.19 TIMx and external trigger synchronization

The TIMx timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so there's no need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 130. Control circuit in reset mode**

### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 131. Control circuit in gated mode**

MS31402V3

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so there's no need to configure it. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx\_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 132. Control circuit in trigger mode**

### Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx\_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS = 00: prescaler disabled
  - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI1:
  - IC1F=0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S=01 in TIMx\_CCMR1 register to select only the input capture source

- CC1P=0 and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 133. Control circuit in external clock mode 2 + trigger mode**

### 17.3.20 Timer synchronization

The TIM timers are linked together internally for timer synchronization or chaining. Refer to [Section 18.3.15: Timer synchronization](#) for details.

*Note:* The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

### 17.3.21 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M4 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBG module. For more details, refer to [Section 38.16.2: Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C](#).

For safety purposes, when the counter is stopped (DBG\_TIMx\_STOP = 1 in DBGMCU\_APBx\_FZ register), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.

## 17.4 TIM1 and TIM8 registers

Refer to [Section 2.2](#) for a list of abbreviations used in register descriptions.

The peripheral registers must be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-word (16 bits) or words (32 bits).

### 17.4.1 TIM1 and TIM8 control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9        | 8   | 7    | 6        | 5   | 4   | 3   | 2   | 1    | 0   |
|----------|----|----|----|----|----|----------|-----|------|----------|-----|-----|-----|-----|------|-----|
| Reserved |    |    |    |    |    | CKD[1:0] |     | ARPE | CMS[1:0] |     | DIR | OPM | URS | UDIS | CEN |
|          |    |    |    |    |    | r/w      | r/w | r/w  | r/w      | r/w | r/w | r/w | r/w | r/w  | r/w |

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and the dead-time and sampling clock ( $t_{DTS}$ ) used by the dead-time generators and the digital filters (ETR, TIX),

00:  $t_{DTS}=t_{CK\_INT}$

01:  $t_{DTS}=2*t_{CK\_INT}$

10:  $t_{DTS}=4*t_{CK\_INT}$

11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).

01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting down.

10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting up.

11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)*

Bit 4 **DIR**: Direction

0: Counter used as upcounter

1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the bit CEN)

**Bit 2 URS:** Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

**Bit 1 UDIS:** Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

**Bit 0 CEN:** Counter enable

0: Counter disabled

1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

**17.4.2 TIM1 and TIM8 control register 2 (TIMx\_CR2)**

Address offset: 0x04

Reset value: 0x0000

| 15   | 14   | 13    | 12   | 11    | 10   | 9     | 8    | 7    | 6        | 5  | 4  | 3    | 2    | 1    | 0    |

| Res. | OIS4 | OIS3N | OIS3 | OIS2N | OIS2 | OIS1N | OIS1 | TI1S | MMS[2:0] |    |    | CCDS | CCUS | Res. | CCPC |
|      | rw   | rw    | rw   | rw    | rw   | rw    | rw   | rw   | rw       | rw | rw | rw   | rw   |      | rw   |

Bit 15 Reserved, must be kept at reset value.

Bit 14 **OIS4**: Output Idle state 4 (OC4 output)  
refer to OIS1 bit

Bit 13 **OIS3N**: Output Idle state 3 (OC3N output)  
refer to OIS1N bit

Bit 12 **OIS3**: Output Idle state 3 (OC3 output)  
refer to OIS1 bit

Bit 11 **OIS2N**: Output Idle state 2 (OC2N output)  
refer to OIS1N bit

Bit 10 **OIS2**: Output Idle state 2 (OC2 output)  
refer to OIS1 bit

Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)

0: OC1N=0 after a dead-time when MOE=0

1: OC1N=1 after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)

0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0

1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 7 **TI1S**: TI1 selection

0: The TIMx\_CH1 pin is connected to TI1 input

1: The TIMx\_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter Enable signal CNT\_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).

010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO).

100: **Compare** - OC1REF signal is used as trigger output (TRGO)

101: **Compare** - OC2REF signal is used as trigger output (TRGO)

110: **Compare** - OC3REF signal is used as trigger output (TRGO)

111: **Compare** - OC4REF signal is used as trigger output (TRGO)

*Note: The clock of the slave timer and ADC must be enabled prior to receiving events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only

1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded

1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*

### 17.4.3 TIM1 and TIM8 slave mode control register (TIMx\_SMCR)

Address offset: 0x08

Reset value: 0x0000

| 15  | 14  | 13        | 12 | 11       | 10 | 9  | 8  | 7   | 6       | 5  | 4  | 3    | 2        | 1  | 0  |
|-----|-----|-----------|----|----------|----|----|----|-----|---------|----|----|------|----------|----|----|
| ETP | ECE | ETPS[1:0] |    | ETF[3:0] |    |    |    | MSM | TS[2:0] |    |    | Res. | SMS[2:0] |    |    |
| rw  | rw  | rw        | rw | rw       | rw | rw | rw | rw  | rw      | rw | rw | Res. | rw       | rw | rw |

Bit 15 **ETP**: External trigger polarity

This bit selects whether ETR or  $\overline{\text{ETR}}$  is used for trigger operations

0: ETR is non-inverted, active at high level or rising edge.

1: ETR is inverted, active at low level or falling edge.

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note:* **1:** Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).

**2:** It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).

**3:** If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

00: Prescaler OFF

01: ETRP frequency divided by 2

10: ETRP frequency divided by 4

11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ ,  $N=2$

0010:  $f_{SAMPLING}=f_{CK\_INT}$ ,  $N=4$

0011:  $f_{SAMPLING}=f_{CK\_INT}$ ,  $N=8$

0100:  $f_{SAMPLING}=f_{DTS}/2$ ,  $N=6$

0101:  $f_{SAMPLING}=f_{DTS}/2$ ,  $N=8$

0110:  $f_{SAMPLING}=f_{DTS}/4$ ,  $N=6$

0111:  $f_{SAMPLING}=f_{DTS}/4$ ,  $N=8$

1000:  $f_{SAMPLING}=f_{DTS}/8$ ,  $N=6$

1001:  $f_{SAMPLING}=f_{DTS}/8$ ,  $N=8$

1010:  $f_{SAMPLING}=f_{DTS}/16$ ,  $N=5$

1011:  $f_{SAMPLING}=f_{DTS}/16$ ,  $N=6$

1100:  $f_{SAMPLING}=f_{DTS}/16$ ,  $N=8$

1101:  $f_{SAMPLING}=f_{DTS}/32$ ,  $N=5$

1110:  $f_{SAMPLING}=f_{DTS}/32$ ,  $N=6$

1111:  $f_{SAMPLING}=f_{DTS}/32$ ,  $N=8$

Bit 7 **MSM**: Master/slave mode

0: No action

1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0)

001: Internal Trigger 1 (ITR1)

010: Internal Trigger 2 (ITR2)

011: Internal Trigger 3 (ITR3)

100: TI1 Edge Detector (TI1F\_ED)

101: Filtered Timer Input 1 (TI1FP1)

110: Filtered Timer Input 2 (TI2FP2)

111: External Trigger input (ETRF)

See [Table 94](#) for more details on ITRx meaning for each Timer.

*Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

## Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SMS**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control register description).

000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.

001: Encoder mode 1 - Counter counts up/down on TI2FP1 edge depending on TI1FP2 level.

010: Encoder mode 2 - Counter counts up/down on TI1FP2 edge depending on TI2FP1 level.

011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.

100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS='100'). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.*

*The clock of the slave timer must be enabled prior to receiving events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Table 94. TIMx Internal trigger connection

| Slave TIM | ITR0 (TS = 000) | ITR1 (TS = 001) | ITR2 (TS = 010) | ITR3 (TS = 011) |
|-----------|-----------------|-----------------|-----------------|-----------------|
| TIM1      | TIM5_TRGO       | TIM2_TRGO       | TIM3_TRGO       | TIM4_TRGO       |
| TIM8      | TIM1_TRGO       | TIM2_TRGO       | TIM4_TRGO       | TIM5_TRGO       |

## 17.4.4 TIM1 and TIM8 DMA/interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

|      | 15  | 14    | 13    | 12    | 11    | 10    | 9   | 8   | 7   | 6     | 5     | 4     | 3     | 2     | 1   | 0  |

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TDE**: Trigger DMA request enable

0: Trigger DMA request disabled

1: Trigger DMA request enabled

Bit 13 **COMDE**: COM DMA request enable

0: COM DMA request disabled

1: COM DMA request enabled

- Bit 12 **CC4DE**: Capture/Compare 4 DMA request enable  
0: CC4 DMA request disabled  
1: CC4 DMA request enabled
- Bit 11 **CC3DE**: Capture/Compare 3 DMA request enable  
0: CC3 DMA request disabled  
1: CC3 DMA request enabled
- Bit 10 **CC2DE**: Capture/Compare 2 DMA request enable  
0: CC2 DMA request disabled  
1: CC2 DMA request enabled
- Bit 9 **CC1DE**: Capture/Compare 1 DMA request enable  
0: CC1 DMA request disabled  
1: CC1 DMA request enabled
- Bit 8 **UDE**: Update DMA request enable  
0: Update DMA request disabled  
1: Update DMA request enabled
- Bit 7 **BIE**: Break interrupt enable  
0: Break interrupt disabled  
1: Break interrupt enabled
- Bit 6 **TIE**: Trigger interrupt enable  
0: Trigger interrupt disabled  
1: Trigger interrupt enabled
- Bit 5 **COMIE**: COM interrupt enable  
0: COM interrupt disabled  
1: COM interrupt enabled
- Bit 4 **CC4IE**: Capture/Compare 4 interrupt enable  
0: CC4 interrupt disabled  
1: CC4 interrupt enabled
- Bit 3 **CC3IE**: Capture/Compare 3 interrupt enable  
0: CC3 interrupt disabled  
1: CC3 interrupt enabled
- Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable  
0: CC2 interrupt disabled  
1: CC2 interrupt enabled
- Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable  
0: CC1 interrupt disabled  
1: CC1 interrupt enabled
- Bit 0 **UIE**: Update interrupt enable  
0: Update interrupt disabled  
1: Update interrupt enabled

### 17.4.5 TIM1 and TIM8 status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

| 15       | 14 | 13 | 12    | 11    | 10    | 9     | 8    | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|----------|----|----|-------|-------|-------|-------|------|-------|-------|-------|-------|-------|-------|-------|-------|
| Reserved |    |    | CC4OF | CC3OF | CC2OF | CC1OF | Res. | BIF   | TIF   | COMIF | CC4IF | CC3IF | CC2IF | CC1IF | UIF   |
|          |    |    | rc_w0 | rc_w0 | rc_w0 | rc_w0 | Res. | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 |

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag  
refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag  
refer to CC1OF description

Bit 10 **CC2OF**: Capture/Compare 2 overcapture flag  
refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag  
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.  
0: No overcapture has been detected.  
1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 **BIF**: Break interrupt flag  
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.  
0: No break event occurred.  
1: An active level has been detected on the break input.

Bit 6 **TIF**: Trigger interrupt flag  
This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.  
0: No trigger event occurred.  
1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag  
This flag is set by hardware on COM event (when Capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.  
0: No COM event occurred.  
1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag  
refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag  
refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag  
refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

**If channel CC1 is configured as output:**

This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx\_CR1 register description). It is cleared by software.

0: No match.

1: The content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)

**If channel CC1 is configured as input:**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred

1: The counter value has been captured in TIMx\_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register.
- When CNT is reinitialized by a trigger event (refer to [Section 17.4.3: TIM1 and TIM8 slave mode control register \(TIMx\\_SMCR\)](#)), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

## 17.4.6 TIM1 and TIM8 event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7  | 6  | 5    | 4    | 3    | 2    | 1    | 0  |
|----------|----|----|----|----|----|---|---|----|----|------|------|------|------|------|----|
| Reserved |    |    |    |    |    |   |   | BG | TG | COMG | CC4G | CC3G | CC2G | CC1G | UG |
|          |    |    |    |    |    |   |   | w  | w  | w    | w    | w    | w    | w    | w  |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 **COMG**: Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware

0: No action

1: When CCPC bit is set, it allows to update CCxE, CCxNE and OCxM bits

*Note: This bit acts only on channels having a complementary output.*

Bit 4 **CC4G**: Capture/Compare 4 generation

refer to CC1G description

Bit 3 **CC3G**: Capture/Compare 3 generation

refer to CC1G description

Bit 2 **CC2G**: Capture/Compare 2 generation

refer to CC1G description

Bit 1 **CC1G**: Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx\_ARR) if DIR=1 (downcounting).

### 17.4.7 TIM1 and TIM8 capture/compare mode register 1 (TIMx\_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So the user must take care that the same bit can have a different meaning for the input stage and for the output stage.

| 15        | 14        | 13 | 12          | 11        | 10        | 9         | 8  | 7           | 6         | 5  | 4  | 3         | 2         | 1         | 0  |
|-----------|-----------|----|-------------|-----------|-----------|-----------|----|-------------|-----------|----|----|-----------|-----------|-----------|----|
| OC2<br>CE | OC2M[2:0] |    |             | OC2<br>PE | OC2<br>FE | CC2S[1:0] |    | OC1<br>CE   | OC1M[2:0] |    |    | OC1<br>PE | OC1<br>FE | CC1S[1:0] |    |
| IC2F[3:0] |           |    | IC2PSC[1:0] |           | IC1F[3:0] |           |    | IC1PSC[1:0] |           |    |    |           |           |           |    |
| rw        | rw        | rw | rw          | rw        | rw        | rw        | rw | rw          | rw        | rw | rw | rw        | rw        | rw        | rw |

#### Output compare mode:

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 14:12 **OC2M[2:0]**: Output compare 2 mode

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note:* CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).

Bit 7 **OC1CE**: Output compare 1 clear enable

OC1CE: Output compare 1 Clear Enable

0: OC1Ref is not affected by the ETRF Input

1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bits 6:4 **OC1M**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs.(this mode is used to generate a timing base).

001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

100: Force inactive level - OC1REF is forced low.

101: Force active level - OC1REF is forced high.

110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT<TIMx\_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx\_CNT>TIMx\_CCR1 else active (OC1REF='1').

111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT<TIMx\_CCR1 else active. In downcounting, channel 1 is active as long as TIMx\_CNT>TIMx\_CCR1 else inactive.

*Note: 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

*2: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

*3: On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S='00' (the channel is configured in output).*

*2: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.  
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).

## Input capture mode

Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx\_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING} = f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING} = f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING} = f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING} = f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING} = f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING} = f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING} = f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING} = f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING} = f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING} = f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING} = f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING} = f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING} = f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING} = f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING} = f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1).

The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S**: Capture/Compare 1 Selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).*

## 17.4.8 TIM1 and TIM8 capture/compare mode register 2 (TIMx\_CCMR2)

Address offset: 0x1C

Reset value: 0x0000

Refer to the above CCMR1 register description.

| 15        | 14        | 13  | 12  | 11          | 10        | 9         | 8         | 7   | 6         | 5           | 4   | 3   | 2   | 1         | 0         |           |  |

### Output compare mode

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 14:12 **OC4M**: Output compare 4 mode

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx\_CCER).*

Bit 7 **OC3CE**: Output compare 3 clear enable

Bits 6:4 **OC3M**: Output compare 3 mode

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx\_CCER).*

## Input capture mode

Bits 15:12 **IC4F**: Input capture 4 filter

Bits 11:10 **IC4PSC**: Input capture 4 prescaler

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx\_CCER).

Bits 7:4 **IC3F**: Input capture 3 filter

Bits 3:2 **IC3PSC**: Input capture 3 prescaler

Bits 1:0 **CC3S**: Capture/compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note:* CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx\_CCER).

### 17.4.9 TIM1 and TIM8 capture/compare enable register (TIMx\_CCER)

Address offset: 0x20

Reset value: 0x0000

Bit 15 **CC4NP**: Capture/Compare 4 complementary output polarity  
refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/Compare 4 output polarity  
refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable  
refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 complementary output polarity  
refer to CC1NP description

Bit 10 **CC3NE**: Capture/Compare 3 complementary output enable  
refer to CC1NE description

Bit 9 **CC3P**: Capture/Compare 3 output polarity  
refer to CC1P description

- Bit 8 **CC3E**: Capture/Compare 3 output enable  
refer to CC1E description
- Bit 7 **CC2NP**: Capture/Compare 2 complementary output polarity  
refer to CC1NP description
- Bit 6 **CC2NE**: Capture/Compare 2 complementary output enable  
refer to CC1NE description
- Bit 5 **CC2P**: Capture/Compare 2 output polarity  
refer to CC1P description
- Bit 4 **CC2E**: Capture/Compare 2 output enable  
refer to CC1E description
- Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity  
CC1 channel configured as output:  
0: OC1N active high.  
1: OC1N active low.  
CC1 channel configured as input:  
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.
- Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.*
- Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S="00" (the channel is configured in output).*
- Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable  
0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.  
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
- Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Bit 1 **CC1P**: Capture/Compare 1 output polarity

**CC1 channel configured as output:**

0: OC1 active high

1: OC1 active low

**CC1 channel configured as input:**

CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

00: non-inverted/rising edge

The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

01: inverted/falling edge

The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

10: reserved, do not use this configuration.

11: non-inverted/both edges

The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

*Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 0 **CC1E**: Capture/Compare 1 output enable

**CC1 channel configured as output:**

0: Off - OC1 is not active. OC1 level is then function of MOE, OSS1, OSSR, OIS1, OIS1N and CC1NE bits.

1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSS1, OSSR, OIS1, OIS1N and CC1NE bits.

**CC1 channel configured as input:**

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.

0: Capture disabled.

1: Capture enabled.

*Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx\_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

Table 95. Output control bits for complementary OCx and OCxN channels with break feature

| Control bits |          |          |          |                                                                                                                                                              | Output states <sup>(1)</sup>                                                                                                        |                                                                         |

|              | 0        |          | 1        | Off-State (output enabled with inactive state)                                                                                                               |                                                                                                                                     |                                                                         |
|              | 1        |          | 0        | Asynchronously: OCx=CCxP, OCx_EN=1, OCxN=CCxNP, OCxN_EN=1                                                                                                    |                                                                                                                                     |                                                                         |
|              | 1        |          | 1        | Then if the clock is present: OCx=OISx and OCxN=OISxN after a dead-time, assuming that OISx and OISxN do not correspond to OCx and OCxN both in active state |                                                                                                                                     |                                                                         |

1. When both outputs of a channel are not used (CCxE = CCxNE = 0), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

**Note:** The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and the GPIO registers.

**17.4.10 TIM1 and TIM8 counter (TIMx\_CNT)**

Address offset: 0x24

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CNT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CNT[15:0]**: Counter value**17.4.11 TIM1 and TIM8 prescaler (TIMx\_PSC)**

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]**: Prescaler valueThe counter clock frequency (CK\_CNT) is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

**17.4.12 TIM1 and TIM8 auto-reload register (TIMx\_ARR)**

Address offset: 0x2C

Reset value: 0xFFFF

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to [Section 17.3.1: Time-base unit](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 17.4.13 TIM1 and TIM8 repetition counter register (TIMx\_RCR)

Address offset: 0x30

Reset value: 0x0000

|          |    |    |    |    |    |   |   |          |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|---|---|----------|----|----|----|----|----|----|----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |   |   | REP[7:0] |    |    |    |    |    |    |    |
|          |    |    |    |    |    |   |   | rw       | rw | rw | rw | rw | rw | rw | rw |

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **REP[7:0]**: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP\_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP\_CNT is reloaded with REP value only at the repetition update event U\_RC, any write to the TIMx\_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to:

- the number of PWM periods in edge-aligned mode
- the number of half PWM period in center-aligned mode.

### 17.4.14 TIM1 and TIM8 capture/compare register 1 (TIMx\_CCR1)

Address offset: 0x34

Reset value: 0x0000

|            |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 15         | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR1[15:0] |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro      | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx\_CCR1 register is read-only and cannot be programmed.

### 17.4.15 TIM1 and TIM8 capture/compare register 2 (TIMx\_CCR2)

Address offset: 0x38

Reset value: 0x0000

|            |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 15         | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR2[15:0] |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro      | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx\_CCR2 register is read-only and cannot be programmed.

### 17.4.16 TIM1 and TIM8 capture/compare register 3 (TIMx\_CCR3)

Address offset: 0x3C

Reset value: 0x0000

|            |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 15         | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR3[15:0] |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro      | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 15:0 **CCR3[15:0]**: Capture/Compare value

**If channel CC3 is configured as output:**

CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR3 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC3 output.

**If channel CC3 is configured as input:**

CCR3 is the counter value transferred by the last input capture 3 event (IC3). The TIMx\_CCR3 register is read-only and cannot be programmed.

### 17.4.17 TIM1 and TIM8 capture/compare register 4 (TIMx\_CCR4)

Address offset: 0x40

Reset value: 0x0000

|            |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 15         | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR4[15:0] |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro      | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 15:0 **CCR4[15:0]**: Capture/Compare value

**If channel CC4 is configured as output:**

CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR4 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC4 output.

**If channel CC4 is configured as input:**

CCR4 is the counter value transferred by the last input capture 4 event (IC4). The TIMx\_CCR3 register is read-only and cannot be programmed.

### 17.4.18 TIM1 and TIM8 break and dead-time register (TIMx\_BDTR)

Address offset: 0x44

Reset value: 0x0000

|     |     |     |     |      |      |           |    |          |    |    |    |    |    |    |    |
|-----|-----|-----|-----|------|------|-----------|----|----------|----|----|----|----|----|----|----|
| 15  | 14  | 13  | 12  | 11   | 10   | 9         | 8  | 7        | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| MOE | AOE | BKP | BKE | OSSR | OSSI | LOCK[1:0] |    | DTG[7:0] |    |    |    |    |    |    |    |
| rw  | rw  | rw  | rw  | rw   | rw   | rw        | rw | rw       | rw | rw | rw | rw | rw | rw | rw |

**Note:** As the bits AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx\_BDTR register.

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: OC and OCN outputs are disabled or forced to idle state.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx\_CCER register).

See OC/OCN enable description for more details ([Section 17.4.9: TIM1 and TIM8 capture/compare enable register \(TIMx\\_CCER\)](#)).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).

Bit 13 **BKP**: Break polarity

- 0: Break input BRK is active low
- 1: Break input BRK is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 12 **BKE**: Break enable

- 0: Break inputs (BRK and CSS clock failure event) disabled
- 1: Break inputs (BRK and CSS clock failure event) enabled

*Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx\_BDTR register).*

*Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.*

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details ([Section 17.4.9: TIM1 and TIM8 capture/compare enable register \(TIMx\\_CCER\)](#)).

- 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0).
- 1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1. Then, OC/OCN enable output signal=1

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details ([Section 17.4.9: TIM1 and TIM8 capture/compare enable register \(TIMx\\_CCER\)](#)).

- 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0).
- 1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx\_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.

01: LOCK Level 1 = DTG bits in TIMx\_BDTR register, OISx and OISxN bits in TIMx\_CR2 register and BKE/BKP/AOE bits in TIMx\_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx\_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx\_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx\_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx =>  $DT = DTG[7:0] \times t_{dtg}$  with  $t_{dtg} = t_{DTS}$ .

DTG[7:5]=10x =>  $DT = (64 + DTG[5:0]) \times t_{dtg}$  with  $T_{dtg} = 2 \times t_{DTS}$ .

DTG[7:5]=110 =>  $DT = (32 + DTG[4:0]) \times t_{dtg}$  with  $T_{dtg} = 8 \times t_{DTS}$ .

DTG[7:5]=111 =>  $DT = (32 + DTG[4:0]) \times t_{dtg}$  with  $T_{dtg} = 16 \times t_{DTS}$ .

Example if  $T_{DTS} = 125\text{ns}$  (8MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 us to 31750 ns by 250 ns steps,

32 us to 63us by 1 us steps,

64 us to 126 us by 2 us steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx\_BDTR register).*

## 17.4.19 TIM1 and TIM8 DMA control register (TIMx\_DCR)

Address offset: 0x48

Reset value: 0x0000

| 15       | 14 | 13 | 12       | 11 | 10 | 9  | 8  | 7        | 6 | 5 | 4        | 3  | 2  | 1  | 0  |
|----------|----|----|----------|----|----|----|----|----------|---|---|----------|----|----|----|----|
| Reserved |    |    | DBL[4:0] |    |    |    |    | Reserved |   |   | DBA[4:0] |    |    |    |    |
|          |    |    | rw       | rw | rw | rw | rw |          |   |   | rw       | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the number of DMA transfers (the timer detects a burst transfer when a read or a write access to the TIMx\_DMAR register address is performed).

the TIMx\_DMAR address)

00000: 1 transfer

00001: 2 transfers

00010: 3 transfers

...

10001: 18 transfers

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1,

00001: TIMx\_CR2,

00010: TIMx\_SMCR,

...

**Example:** Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx\_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx\_CR1 address.

## 17.4.20 TIM1 and TIM8 DMA address for full transfer (TIMx\_DMAR)

Address offset: 0x4C

Reset value: 0x0000 0000

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address  
 $(\text{TIMx\_CR1 address}) + (\text{DBA} + \text{DMA index}) \times 4$

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).

### Example of how to use the DMA burst feature

In this example the timer DMA burst feature is used to update the contents of the CCRx registers ( $x = 2, 3, 4$ ) with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
  - DMA channel peripheral address is the DMAR register address
  - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
  - Number of data to transfer = 3 (See note below).
  - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:  
 DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

**Note:** *This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.*

TIM1 and TIM8 registers are mapped as 16-bit addressable registers as described in the table below:

[illegible]

Table 96. TIM1 and TIM8 register map and reset values (continued)

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 18 General-purpose timers (TIM2 to TIM5)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 18.1 TIM2 to TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (*input capture*) or generating output waveforms (*output compare and PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 18.3.15](#).

### 18.2 TIM2 to TIM5 main features

General-purpose TIMx timer features include:

- 16-bit (TIM3 and TIM4) or 32-bit (TIM2 and TIM5) up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65536.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

Figure 134. General-purpose timer block diagram

## 18.3 TIM2 to TIM5 functional description

### 18.3.1 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC):
- Auto-Reload register (TIMx\_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

[Figure 135](#) and [Figure 136](#) give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 135. Counter timing diagram with prescaler division change from 1 to 2****Figure 136. Counter timing diagram with prescaler division change from 1 to 4**

### 18.3.2 Counter modes

#### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate

does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

**Figure 137. Counter timing diagram, internal clock divided by 1**

**Figure 141. Counter timing diagram, Update event when ARPE=0 (TIMx\_ARR not preloaded)**

**Figure 142. Counter timing diagram, Update event when ARPE=1 (TIMx\_ARR preloaded)**

### Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx\_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller)

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the

preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

**Figure 143. Counter timing diagram, internal clock divided by 1**

Figure 144. Counter timing diagram, internal clock divided by 2

Figure 145. Counter timing diagram, internal clock divided by 4

Figure 146. Counter timing diagram, internal clock divided by N

Figure 147. Counter timing diagram, Update event

### Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx\_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx\_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 148. Counter timing diagram, internal clock divided by 1, TIMx\_ARR=0x6**

1. Here, center-aligned mode 1 is used, for more details refer to [Section 18.4.1: TIMx control register 1 \(TIMx\\_CR1\)](#).

Figure 153. Counter timing diagram, Update event with ARPE=1 (counter overflow)

### 18.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR) available on TIM2, TIM3 and TIM4 only.
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, Timer3 can be configured to act as a prescaler for Timer 2. Refer to [Using one timer as prescaler for another timer](#) for more details.

#### Internal clock source (CK\_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx\_SMCR register), then the CEN, DIR (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 154](#) shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 154. Control circuit in normal mode, internal clock divided by 1**

#### External clock source mode 1

This mode is selected when SMS=111 in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 155. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S= '01 in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F=0000).

**Note:** The capture prescaler is not used for triggering, so there's no need to configure it.

3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx\_SMCR register.
5. Select TI2 as the input source by writing TS=110 in the TIMx\_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

Figure 156. Control circuit in external clock mode 1

### External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx\_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

Figure 157 gives an overview of the external trigger input block.

Figure 157. External trigger input block

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx\_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx\_SMCR register
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx\_SMCR register
4. Enable external clock mode 2 by writing ECE=1 in the TIMx\_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

**Figure 158. Control circuit in external clock mode 2**

### 18.3.4 Capture/compare channels

Each Capture/Compare channel (see [Figure 159](#)) is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

**Figure 159. Capture/compare channel (example: channel 1 input stage)**

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

Figure 160. Capture/compare channel 1 main circuit

MS33144V1

Figure 161. Output stage of capture/compare channel (channel 1)

ai17187b

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 18.3.5 Input capture mode

In Input capture mode, the Capture/Compare registers (TIMx\_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx\_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx\_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when written to 0.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx\_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx\_CCR1 register becomes read-only.
- Program the needed input filter duration with respect to the signal connected to the timer (by programming the ICxF bits in the TIMx\_CCMRx register if the input is one of the TIx inputs). Let's imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on TI1 when eight consecutive samples with the new level have been detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to 0011 in the TIMx\_CCMR1 register.
- Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP bits to 00 in the TIMx\_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx\_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 18.3.6 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

- Select the active input for TIMx\_CCR1: write the CC1S bits to 01 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): write the CC1P to '0' and the CC1NP bit to '0' (active on rising edge).
- Select the active input for TIMx\_CCR2: write the CC2S bits to 10 in the TIMx\_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): write the CC2P bit to '1' and the CC2NP bit to '0' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx\_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx\_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

**Figure 162. PWM input mode timing**

### 18.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (ocxref/OCx) to its active level, the user just needs to write 101 in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus ocxref is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

e.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the next section.

### 18.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx\_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx\_DIER register, CCDS bit in the TIMx\_CR2 register for the DMA request selection).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on ocxref and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, the user must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 163](#).

**Figure 163. Output compare mode, toggle on OC1**

### 18.3.9 PWM mode

Pulse width modulation mode allows generating a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or '111 (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. The user must enable the corresponding preload register by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, the user has to initialize all the registers by setting the UG bit in the TIMx\_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx\_CCER register. Refer to the TIMx\_CCERx register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CCRx \leq TIMx\_CNT$  or  $TIMx\_CNT \leq TIMx\_CCRx$  (depending on the direction of the counter). However, to comply with the ETRF (OCREF can be cleared by an external event through the ETR signal until the next PWM period), the OCREF signal is asserted only:

- When the result of the comparison changes, or
- When the output compare mode (OCxM bits in TIMx\_CCMRx register) switches from the "frozen" configuration (no comparison, OCxM='000) to one of the PWM modes (OCxM='110 or '111).

This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx\_CR1 register.

### PWM edge-aligned mode

#### Upcounting configuration

Upcounting is active when the DIR bit in the TIMx\_CR1 register is low. Refer to [Upcounting mode](#).

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the compare value in TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxREF is held at '0'. [Figure 164](#) shows some edge-aligned PWM waveforms in an example where  $TIMx\_ARR=8$ .

**Figure 164. Edge-aligned PWM waveforms (ARR=8)**

#### Downcounting configuration

Downcounting is active when DIR bit in TIMx\_CR1 register is high. Refer to [Downcounting mode](#).

In PWM mode 1, the reference signal ocxref is low as long as  $TIMx\_CNT > TIMx\_CCRx$  else it becomes high. If the compare value in TIMx\_CCRx is greater than the auto-reload value in TIMx\_ARR, then ocxref is held at '1'. 0% PWM is not possible in this mode.

### PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx\_CR1 register are different from '00' (all the remaining configurations having the same effect on the ocxref/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts

up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx\_CR1 register is updated by hardware and must not be changed by software. Refer to [Center-aligned mode \(up/down counting\)](#).

Figure 165 shows some center-aligned PWM waveforms in an example where:

- TIMx\_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx\_CR1 register.

**Figure 165. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

in the TIMx\_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if the user writes a value in the counter that is greater than the auto-reload value ( $TIMx\_CNT > TIMx\_ARR$ ). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if the user writes 0 or write the TIMx\_ARR value in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx\_EGR register) just before starting the counter and not to write the counter while it is running.

### 18.3.10 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. Select One-pulse mode by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting:  $CNT < CCRx \leq ARR$  (in particular,  $0 < CCRx$ ),
- In downcounting:  $CNT > CCRx$ .

**Figure 166. Example of one-pulse mode**

MS31099V1

For example the user may want to generate a positive pulse on OC1 with a length of  $t_{PULSE}$  and after a delay of  $t_{DELAY}$  as soon as a positive edge is detected on the TI2 input pin.

Let's use TI2FP2 as trigger 1:

- Map TI2FP2 on TI2 by writing CC2S=01 in the TIMx\_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx\_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=110 in the TIMx\_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to '110 in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR + 1).
- Let us say user wants to build a waveform with a transition from '0 to '1 when a compare match occurs and a transition from '1 to '0 when the counter reaches the auto-reload value. To do this enable PWM mode 2 by writing OC1M=111 in the TIMx\_CCMR1 register. The user can optionally enable the preload registers by writing OC1PE=1 in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0 in this example.

In our example, the DIR and CMS bits in the TIMx\_CR1 register should be low.

User only wants one pulse (Single mode), so write '1 in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive mode is selected.

#### Particular case: OCx fast enable:

In One-pulse mode, the edge detection on Tlx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY min}}$  we can get.

To output a waveform with the minimum delay, the user can set the OCxFE bit in the TIMx\_CCMRx register. Then OCxRef (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 18.3.11 Clearing the OCxREF signal on an external event

The OCxREF signal for a given channel can be driven Low by applying a High level to the ETRF input (OCxCE enable bit of the corresponding TIMx\_CCMRx register set to '1'). The OCxREF signal remains Low until the next update event, UEV, occurs.

This function can only be used in output compare and PWM modes, and does not work in forced mode.

For example, the ETR signal can be connected to the output of a comparator to be used for current handling. In this case, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx\_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1\_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

Figure 167 shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

**Figure 167. Clearing TIMx OCxREF**

1. In case of a PWM with a 100% duty cycle (if CCRx>ARR), OCxREF is enabled again at the next counter overflow.

### 18.3.12 Encoder interface mode

To select Encoder Interface mode write SMS='001' in the TIMx\_SMCR register if the counter is counting on TI2 edges only, SMS=010 if it is counting on TI1 edges only and SMS=011 if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx\_CCER register. When needed, program the input filter as well.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to [Table 97](#). The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx\_CR1 register written to '1'). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx\_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx\_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the user must configure TIMx\_ARR before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the incremental encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 don't switch at the same time.

**Table 97. Counting direction versus encoder signals**

| Active edge             | Level on opposite signal (TI1FP1 for TI2, TI2FP2 for TI1) | TI1FP1 signal |          | TI2FP2 signal |          |
|-------------------------|-----------------------------------------------------------|---------------|----------|---------------|----------|
|                         |                                                           | Rising        | Falling  | Rising        | Falling  |
| Counting on TI1 only    | High                                                      | Down          | Up       | No Count      | No Count |
|                         | Low                                                       | Up            | Down     | No Count      | No Count |
| Counting on TI2 only    | High                                                      | No Count      | No Count | Up            | Down     |
|                         | Low                                                       | No Count      | No Count | Down          | Up       |
| Counting on TI1 and TI2 | High                                                      | Down          | Up       | Up            | Down     |
|                         | Low                                                       | Up            | Down     | Down          | Up       |

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

[Figure 168](#) gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= '01' (TIMx\_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S= '01' (TIMx\_CCMR2 register, TI2FP2 mapped on TI2)
- CC1P= '0', CC1NP = '0', IC1F = '0000' (TIMx\_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P= '0', CC2NP = '0', IC2F = '0000' (TIMx\_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS= '011' (TIMx\_SMCR register, both inputs are active on both rising and falling edges)
- CEN = 1 (TIMx\_CR1 register, Counter is enabled)

**Figure 168. Example of counter operation in encoder interface mode**

Figure 169 gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P=1).

**Figure 169. Example of encoder interface mode with TI1FP1 polarity inverted**

The timer, when configured in Encoder Interface mode provides information on the sensor's current position. The user can obtain dynamic information (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. The user can do this by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request generated by a Real-Time clock.

### 18.3.13 Timer input XOR function

The TI1S bit in the TIM\_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx\_CH1 to TIMx\_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

### 18.3.14 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

#### Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx\_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx\_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Start the counter by writing CEN=1 in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx\_DIER register).

[Figure 170](#) shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 170. Control circuit in reset mode**

### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. The CC1S bits select the input capture source only, CC1S=01 in TIMx\_CCMR1 register. Write CC1P=1 in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 171. Control circuit in gated mode**

1. The configuration "CCxP=CCxNP=1" (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

### Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so the user does not need to configure it. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx\_CCMR1 register. Write CC2P=1 in TIMx\_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 172. Control circuit in trigger mode**

### Slave mode: External Clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx\_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx\_SMCR register as follows:
  - ETF = 0000: no filter
  - ETPS = 00: prescaler disabled
  - ETP = 0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI1:
  - IC1F = 0000: no filter.
  - The capture prescaler is not used for triggering and does not need to be configured.
  - CC1S = 01 in TIMx\_CCMR1 register to select only the input capture source
  - CC1P = 0 in TIMx\_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx\_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx\_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

Figure 173. Control circuit in external clock mode 2 + trigger mode

### 18.3.15 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master mode, it can reset, start, stop or clock the counter of another Timer configured in Slave mode.

[Figure 174](#) presents an overview of the trigger selection and the master mode selection blocks.

**Note:** *The clock of the slave timer must be enabled prior to receiving events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

#### Using one timer as prescaler for another timer

Figure 174. Master/Slave timer example

For example, the user can configure Timer 1 to act as a prescaler for Timer 2 (see [Figure 174](#)). To do this:

- Configure Timer 1 in master mode so that it outputs a periodic trigger signal on each update event UEV. If you write MMS=010 in the TIM1\_CR2 register, a rising edge is output on TRGO1 each time an update event is generated.
- To connect the TRGO1 output of Timer 1 to Timer 2, Timer 2 must be configured in slave mode using ITR0 as internal trigger. You select this through the TS bits in the TIM2\_SMCR register (writing TS=000).
- Then you put the slave mode controller in external clock mode 1 (write SMS=111 in the TIM2\_SMCR register). This causes Timer 2 to be clocked by the rising edge of the periodic Timer 1 trigger signal (which correspond to the timer 1 counter overflow).
- Finally both timers must be enabled by setting their respective CEN bits (TIMx\_CR1 register).

**Note:** If OCx is selected on Timer 1 as trigger output (MMS=1xx), its rising edge is used to clock the counter of timer 2.

### Using one timer to enable another timer

In this example, we control the enable of Timer 2 with the output compare 1 of Timer 1. Refer to [Figure 174](#) for connections. Timer 2 counts on the divided internal clock only when OC1REF of Timer 1 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

- Configure Timer 1 master mode to send its Output compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM1\_CR2 register).
- Configure the Timer 1 OC1REF waveform (TIM1\_CCMR1 register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2\_SMCR register).
- Configure Timer 2 in gated mode (SMS=101 in TIM2\_SMCR register).
- Enable Timer 2 by writing '1' in the CEN bit (TIM2\_CR1 register).
- Start Timer 1 by writing '1' in the CEN bit (TIM1\_CR1 register).

**Note:** The counter 2 clock is not synchronized with counter 1, this mode only affects the Timer 2 counter enable signal.

**Figure 175. Gating timer 2 with OC1REF of timer 1**

In the example in [Figure 175](#), the Timer 2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting Timer 1. You can then write any value

you want in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx\_EGR registers.

In the next example, we synchronize Timer 1 and Timer 2. Timer 1 is the master and starts from 0. Timer 2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. Timer 2 stops when Timer 1 is disabled by writing '0 to the CEN bit in the TIM1\_CR1 register:

- Configure Timer 1 master mode to send its Output compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM1\_CR2 register).
- Configure the Timer 1 OC1REF waveform (TIM1\_CCMR1 register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2\_SMCR register).
- Configure Timer 2 in gated mode (SMS=101 in TIM2\_SMCR register).
- Reset Timer 1 by writing '1 in UG bit (TIM1\_EGR register).
- Reset Timer 2 by writing '1 in UG bit (TIM2\_EGR register).
- Initialize Timer 2 to 0xE7 by writing '0xE7' in the timer 2 counter (TIM2\_CNT).
- Enable Timer 2 by writing '1 in the CEN bit (TIM2\_CR1 register).
- Start Timer 1 by writing '1 in the CEN bit (TIM1\_CR1 register).
- Stop Timer 1 by writing '0 in the CEN bit (TIM1\_CR1 register).

**Figure 176. Gating timer 2 with Enable of timer 1**

### Using one timer to start another timer

In this example, we set the enable of Timer 2 with the update event of Timer 1. Refer to [Figure 174](#) for connections. Timer 2 starts counting from its current value (which can be nonzero) on the divided internal clock as soon as the update event is generated by Timer 1. When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write '0 to the CEN bit in the TIM2\_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK\_INT ( $f_{CK\_CNT} = f_{CK\_INT}/3$ ).

- Configure Timer 1 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM1\_CR2 register).
- Configure the Timer 1 period (TIM1\_ARR registers).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2\_SMCR register).
- Configure Timer 2 in trigger mode (SMS=110 in TIM2\_SMCR register).
- Start Timer 1 by writing '1 in the CEN bit (TIM1\_CR1 register).

**Figure 177. Triggering timer 2 with update of timer 1**

As in the previous example, the user can initialize both counters before starting counting. [Figure 178](#) shows the behavior with the same configuration as in [Figure 177](#) but in trigger mode instead of gated mode (SMS=110 in the TIM2\_SMCR register).

Figure 178. Triggering timer 2 with Enable of timer 1

MS37391V1

### Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of timer 1 when its TI1 input rises, and the enable of Timer 2 with the enable of Timer 1. Refer to [Figure 174](#) for connections. To ensure the counters are aligned, Timer 1 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to Timer 2):

- Configure Timer 1 master mode to send its Enable as trigger output (MMS=001 in the TIM1\_CR2 register).
- Configure Timer 1 slave mode to get the input trigger from TI1 (TS=100 in the TIM1\_SMCR register).
- Configure Timer 1 in trigger mode (SMS=110 in the TIM1\_SMCR register).
- Configure the Timer 1 in Master/Slave mode by writing MSM=1 (TIM1\_SMCR register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2\_SMCR register).
- Configure Timer 2 in trigger mode (SMS=110 in the TIM2\_SMCR register).

When a rising edge occurs on TI1 (Timer 1), both counters start counting synchronously on the internal clock and both TIF flags are set.

**Note:**

*In this example both timers are initialized before starting (by setting their respective UG bits). Both counters start from 0, but you can easily insert an offset between them by writing any of the counter registers (TIMx\_CNT). You can see that the master/slave mode insert a delay between CNT\_EN and CK\_PSC on timer 1.*

Figure 179. Triggering timer 1 and 2 with timer 1 TI1 input

### 18.3.16 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M4 with FPU core - halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBGMCU module. For more details, refer to [Section 38.16.2: Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C](#).

## 18.4 TIM2 to TIM5 registers

Refer to [Section 2.2](#) for a list of abbreviations used in register descriptions.

The 32-bit peripheral registers have to be written by words (32 bits). All other peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

### 18.4.1 TIMx control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9        | 8   | 7    | 6   | 5   | 4   | 3   | 2   | 1    | 0   |
|----------|----|----|----|----|----|----------|-----|------|-----|-----|-----|-----|-----|------|-----|
| Reserved |    |    |    |    |    | CKD[1:0] |     | ARPE | CMS |     | DIR | OPM | URS | UDIS | CEN |
|          |    |    |    |    |    | r/w      | r/w | r/w  | r/w | r/w | r/w | r/w | r/w | r/w  | r/w |

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **CKD**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (ETR, TIX),

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 \times t_{CK\_INT}$

10:  $t_{DTS} = 4 \times t_{CK\_INT}$

11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:5 **CMS**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).

01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting down.

10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set only when the counter is counting up.

11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx\_CCMRx register) are set both when the counter is counting up or down.

*Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)*

Bit 4 **DIR**: Direction

0: Counter used as upcounter

1: Counter used as downcounter

*Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.*

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the bit CEN)

**Bit 2 URS:** Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

**Bit 1 UDIS:** Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

**Bit 0 CEN:** Counter enable

0: Counter disabled

1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

## 18.4.2 TIMx control register 2 (TIMx\_CR2)

Address offset: 0x04

Reset value: 0x0000

|          |    |    |    |    |    |   |   |      |          |    |    |      |          |   |   |
|----------|----|----|----|----|----|---|---|------|----------|----|----|------|----------|---|---|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6        | 5  | 4  | 3    | 2        | 1 | 0 |
| Reserved |    |    |    |    |    |   |   | TI1S | MMS[2:0] |    |    | CCDS | Reserved |   |   |
|          |    |    |    |    |    |   |   | rw   | rw       | rw | rw | rw   |          |   |   |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TI1S**: TI1 selection

0: The TIMx\_CH1 pin is connected to TI1 input

1: The TIMx\_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx\_SMCR register).

010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO)

100: **Compare** - OC1REF signal is used as trigger output (TRGO)

101: **Compare** - OC2REF signal is used as trigger output (TRGO)

110: **Compare** - OC3REF signal is used as trigger output (TRGO)

111: **Compare** - OC4REF signal is used as trigger output (TRGO)

*Note: The clock of the slave timer and ADC must be enabled prior to receiving events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bits 2:0 Reserved, must be kept at reset value.

### 18.4.3 TIMx slave mode control register (TIMx\_SMCR)

Address offset: 0x08

Reset value: 0x0000

| 15  | 14  | 13        | 12  | 11       | 10  | 9   | 8   | 7   | 6       | 5   | 4   | 3    | 2        | 1   | 0   |
|-----|-----|-----------|-----|----------|-----|-----|-----|-----|---------|-----|-----|------|----------|-----|-----|
| ETP | ECE | ETPS[1:0] |     | ETF[3:0] |     |     |     | MSM | TS[2:0] |     |     | Res. | SMS[2:0] |     |     |
| r/w | r/w | r/w       | r/w | r/w      | r/w | r/w | r/w | r/w | r/w     | r/w | r/w |      | r/w      | r/w | r/w |

Bit 15 **ETP**: External trigger polarity

This bit selects whether ETR or  $\overline{\text{ETR}}$  is used for trigger operations

0: ETR is noninverted, active at high level or rising edge

1: ETR is inverted, active at low level or falling edge

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

1: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).

2: It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).

3: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.

Bits 13:12 **ETPS**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of CK\_INT frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

00: Prescaler OFF

01: ETRP frequency divided by 2

10: ETRP frequency divided by 4

11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{\text{DTS}}$

0001:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=2

0010:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=4

0011:  $f_{\text{SAMPLING}} = f_{\text{CK\_INT}}$ , N=8

0100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=6

0101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/2$ , N=8

0110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=6

0111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/4$ , N=8

1000:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=6

1001:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/8$ , N=8

1010:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=5

1011:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=6

1100:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/16$ , N=8

1101:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=5

1110:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=6

1111:  $f_{\text{SAMPLING}} = f_{\text{DTS}}/32$ , N=8

Bit 7 **MSM**: Master/Slave mode

0: No action

1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0)

001: Internal Trigger 1 (ITR1).

010: Internal Trigger 2 (ITR2).

011: Internal Trigger 3 (ITR3).

100: TI1 Edge Detector (TI1F\_ED)

101: Filtered Timer Input 1 (TI1FP1)

110: Filtered Timer Input 2 (TI2FP2)

111: External Trigger input (ETRF)

See [Table 98: TIMx internal trigger connection on page 632](#) for more details on ITRx meaning for each Timer.*Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

## Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SMS**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control register description).

000: Slave mode disabled - if CEN = '1 then the prescaler is clocked directly by the internal clock.

001: Encoder mode 1 - Counter counts up/down on TI2FP1 edge depending on TI1FP2 level.

010: Encoder mode 2 - Counter counts up/down on TI1FP2 edge depending on TI2FP1 level.

011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.

100: Reset mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

101: Gated mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

110: Trigger mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

111: External Clock mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

*Note: The gated mode must not be used if TI1F\_ED is selected as the trigger input (TS=100). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.**The clock of the slave timer must be enabled prior to receiving events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Table 98. TIMx internal trigger connection

| Slave TIM | ITR0 (TS = 000) | ITR1 (TS = 001) | ITR2 (TS = 010) | ITR3 (TS = 011) |
|-----------|-----------------|-----------------|-----------------|-----------------|
| TIM2      | TIM1_TRGO       | TIM8_TRGO       | TIM3_TRGO       | TIM4_TRGO       |
| TIM3      | TIM1_TRGO       | TIM2_TRGO       | TIM5_TRGO       | TIM4_TRGO       |
| TIM4      | TIM1_TRGO       | TIM2_TRGO       | TIM3_TRGO       | TIM8_TRGO       |
| TIM5      | TIM2_TRGO       | TIM3_TRGO       | TIM4_TRGO       | TIM8_TRGO       |

#### 18.4.4 TIMx DMA/Interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

| 15   | 14  | 13  | 12    | 11    | 10    | 9     | 8   | 7    | 6   | 5   | 4     | 3     | 2     | 1     | 0   |

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TDE**: Trigger DMA request enable  
 0: Trigger DMA request disabled.  
 1: Trigger DMA request enabled.

Bit 13 Reserved, always read as 0

Bit 12 **CC4DE**: Capture/Compare 4 DMA request enable  
 0: CC4 DMA request disabled.  
 1: CC4 DMA request enabled.

Bit 11 **CC3DE**: Capture/Compare 3 DMA request enable  
 0: CC3 DMA request disabled.  
 1: CC3 DMA request enabled.

Bit 10 **CC2DE**: Capture/Compare 2 DMA request enable  
 0: CC2 DMA request disabled.  
 1: CC2 DMA request enabled.

Bit 9 **CC1DE**: Capture/Compare 1 DMA request enable  
 0: CC1 DMA request disabled.  
 1: CC1 DMA request enabled.

Bit 8 **UDE**: Update DMA request enable  
 0: Update DMA request disabled.  
 1: Update DMA request enabled.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TIE**: Trigger interrupt enable  
 0: Trigger interrupt disabled.  
 1: Trigger interrupt enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IE**: Capture/Compare 4 interrupt enable  
 0: CC4 interrupt disabled.  
 1: CC4 interrupt enabled.

Bit 3 **CC3IE**: Capture/Compare 3 interrupt enable

0: CC3 interrupt disabled

1: CC3 interrupt enabled

Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable

0: CC2 interrupt disabled

1: CC2 interrupt enabled

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable

0: CC1 interrupt disabled

1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled

1: Update interrupt enabled

### 18.4.5 TIMx status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

| 15       | 14 | 13 | 12    | 11    | 10    | 9     | 8        | 7 | 6     | 5   | 4     | 3     | 2     | 1     | 0   |
|----------|----|----|-------|-------|-------|-------|----------|---|-------|-----|-------|-------|-------|-------|-----|
| Reserved |    |    | CC4OF | CC3OF | CC2OF | CC1OF | Reserved |   | TIF   | Res | CC4IF | CC3IF | CC2IF | CC1IF | UIF |
|          |    |    | rc_w0 | rc_w0 | rc_w0 | rc_w0 |          |   | rc_w0 |     | rc_w0 | rc_w0 | rc_w0 | rc_w0 |     |

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag

refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag

refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag

refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0.

0: No overcapture has been detected

1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred

1: Trigger interrupt pending

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag

refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag  
refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag  
refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag

**If channel CC1 is configured as output:**

This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx\_CR1 register description). It is cleared by software.

0: No match

1: The content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register.

When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)

**If channel CC1 is configured as input:**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred

1: The counter value has been captured in TIMx\_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

Bit 0 **UIF**: Update interrupt flag

” This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

” At overflow or underflow (for TIM2 to TIM5) and if UDIS=0 in the TIMx\_CR1 register.

” When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS=0 and UDIS=0 in the TIMx\_CR1 register.

When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx\_CR1 register.

### 18.4.6 TIMx event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6  | 5    | 4    | 3    | 2    | 1    | 0  |
|----------|----|----|----|----|----|---|---|---|----|------|------|------|------|------|----|
| Reserved |    |    |    |    |    |   |   |   | TG | Res. | CC4G | CC3G | CC2G | CC1G | UG |
|          |    |    |    |    |    |   |   |   | W  |      | W    | W    | W    | W    | W  |

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIMx\_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation

refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation

refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation

refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx\_ARR) if DIR=1 (downcounting).

### 18.4.7 TIMx capture/compare mode register 1 (TIMx\_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. Take care that the same bit can have a different meaning for the input stage and for the output stage.

| 15        | 14        | 13 | 12 | 11          | 10    | 9         | 8  | 7         | 6         | 5  | 4           | 3     | 2     | 1         | 0  |
|-----------|-----------|----|----|-------------|-------|-----------|----|-----------|-----------|----|-------------|-------|-------|-----------|----|
| OC2CE     | OC2M[2:0] |    |    | OC2PE       | OC2FE | CC2S[1:0] |    | OC1CE     | OC1M[2:0] |    |             | OC1PE | OC1FE | CC1S[1:0] |    |
| IC2F[3:0] |           |    |    | IC2PSC[1:0] |       |           |    | IC1F[3:0] |           |    | IC1PSC[1:0] |       |       |           |    |
| rw        | rw        | rw | rw | rw          | rw    | rw        | rw | rw        | rw        | rw | rw          | rw    | rw    | rw        | rw |

#### Output compare mode

Bit 15 **OC2CE**: Output compare 2 clear enable

Bits 14:12 **OC2M[2:0]**: Output compare 2 mode

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bit 7 **OC1CE**: Output compare 1 clear enable

OC1CE: Output compare 1 Clear Enable

0: OC1Ref is not affected by the ETRF input

1: OC1Ref is cleared as soon as a High level is detected on ETRF input

Bits 6:4 **OC1M**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs. (this mode is used to generate a timing base).

001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1.

100: Force inactive level - OC1REF is forced low.

101: Force active level - OC1REF is forced high.

110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT < TIMx\_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF=0) as long as TIMx\_CNT > TIMx\_CCR1 else active (OC1REF=1).

111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT < TIMx\_CCR1 else active. In downcounting, channel 1 is active as long as TIMx\_CNT > TIMx\_CCR1 else inactive.

*Note: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: 1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx\_BDTR register) and CC1S=00 (the channel is configured in output).*

*2: The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.  
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, IC1 is mapped on TI1.

10: CC1 channel is configured as input, IC1 is mapped on TI2.

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.

01: CC2 channel is configured as input, IC2 is mapped on TI2.

10: CC2 channel is configured as input, IC2 is mapped on TI1.

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bits 7:4 **IC1F**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1).

The prescaler is reset as soon as CC1E=0 (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

### 18.4.8 TIMx capture/compare mode register 2 (TIMx\_CCMR2)

Address offset: 0x1C

Reset value: 0x0000

Refer to the above CCMR1 register description.

| 15        | 14        | 13  | 12  | 11          | 10    | 9         | 8   | 7         | 6         | 5   | 4           | 3     | 2     | 1         | 0   |

#### Output compare mode

Bit 15 **OC4CE**: Output compare 4 clear enable

Bits 14:12 **OC4M**: Output compare 4 mode

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx\_CCER).*

Bit 7 **OC3CE**: Output compare 3 clear enable

Bits 6:4 **OC3M**: Output compare 3 mode

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx\_CCER).*

### Input capture mode

Bits 15:12 **IC4F**: Input capture 4 filter

Bits 11:10 **IC4PSC**: Input capture 4 prescaler

Bits 9:8 **CC4S**: Capture/Compare 4 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, IC4 is mapped on TI4

10: CC4 channel is configured as input, IC4 is mapped on TI3

11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx\_CCER).*

Bits 7:4 **IC3F**: Input capture 3 filter

Bits 3:2 **IC3PSC**: Input capture 3 prescaler

Bits 1:0 **CC3S**: Capture/Compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, IC3 is mapped on TI3

10: CC3 channel is configured as input, IC3 is mapped on TI4

11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx\_CCER).*

## 18.4.9 TIMx capture/compare enable register (TIMx\_CCER)

Address offset: 0x20

Reset value: 0x0000

| 15    | 14   | 13   | 12   | 11    | 10   | 9    | 8    | 7     | 6    | 5    | 4    | 3     | 2    | 1    | 0    |
|-------|------|------|------|-------|------|------|------|-------|------|------|------|-------|------|------|------|
| CC4NP | Res. | CC4P | CC4E | CC3NP | Res. | CC3P | CC3E | CC2NP | Res. | CC2P | CC2E | CC1NP | Res. | CC1P | CC1E |
| rw    |      | rw   | rw   | rw    |      | rw   | rw   | rw    |      | rw   | rw   | rw    |      | rw   | rw   |

Bit 15 **CC4NP**: Capture/Compare 4 output Polarity.

Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/Compare 4 output Polarity.

refer to CC1P description

Bit 12 **CC4E**: Capture/Compare 4 output enable.

refer to CC1E description

Bit 11 **CC3NP**: Capture/Compare 3 output Polarity.

refer to CC1NP description

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC3P**: Capture/Compare 3 output Polarity.

refer to CC1P description

- Bit 8 **CC3E**: *Capture/Compare 3 output enable.*  
refer to CC1E description
- Bit 7 **CC2NP**: *Capture/Compare 2 output Polarity.*  
refer to CC1NP description
- Bit 6 Reserved, must be kept at reset value.
- Bit 5 **CC2P**: *Capture/Compare 2 output Polarity.*  
refer to CC1P description
- Bit 4 **CC2E**: *Capture/Compare 2 output enable.*  
refer to CC1E description
- Bit 3 **CC1NP**: *Capture/Compare 1 output Polarity.*  
CC1 channel configured as output:  
CC1NP must be kept cleared in this case.  
CC1 channel configured as input:  
This bit is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity. refer to CC1P description.
- Bit 2 Reserved, must be kept at reset value.
- Bit 1 **CC1P**: *Capture/Compare 1 output Polarity.*  
**CC1 channel configured as output:**  
0: OC1 active high  
1: OC1 active low  
**CC1 channel configured as input:**  
CC1NP/CC1P bits select TI1FP1 and TI2FP1 polarity for trigger or capture operations.  
00: noninverted/rising edge  
Circuit is sensitive to TIxFP1 rising edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode, encoder mode).  
01: inverted/falling edge  
Circuit is sensitive to TIxFP1 falling edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is inverted (trigger in gated mode, encoder mode).  
10: reserved, do not use this configuration.  
11: noninverted/both edges  
Circuit is sensitive to both TIxFP1 rising and falling edges (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode). This configuration must not be used for encoder mode.
- Bit 0 **CC1E**: *Capture/Compare 1 output enable.*  
**CC1 channel configured as output:**  
0: Off - OC1 is not active  
1: On - OC1 signal is output on the corresponding output pin  
**CC1 channel configured as input:**  
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.  
0: Capture disabled  
1: Capture enabled

**Table 99. Output control bit for standard OCx channels**

| CCxE bit | OCx output state                  |
|----------|-----------------------------------|
| 0        | Output Disabled (OCx=0, OCx_EN=0) |
| 1        | OCx=OCxREF + Polarity, OCx_EN=1   |

**Note:** The state of the external IO pins connected to the standard OCx channels depends on the OCx channel state and the GPIO registers.

#### 18.4.10 TIMx counter (TIMx\_CNT)

Address offset: 0x24

Reset value: 0x0000 0000

|                                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31                               | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CNT[31:16] (depending on timers) |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW                               | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15                               | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CNT[15:0]                        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW                               | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **CNT[31:16]**: High counter value (on TIM2 and TIM5).

Bits 15:0 **CNT[15:0]**: Counter value

#### 18.4.11 TIMx prescaler (TIMx\_PSC)

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

#### 18.4.12 TIMx auto-reload register (TIMx\_ARR)

Address offset: 0x2C

Reset value: 0xFFFF FFFF

|                                  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|----------------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31                               | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| ARR[31:16] (depending on timers) |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW                               | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |
| 15                               | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0]                        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW                               | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:16 **ARR[31:16]**: High auto-reload value (on TIM2 and TIM5).

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the [Section 18.3.1: Time-base unit](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 18.4.13 TIMx capture/compare register 1 (TIMx\_CCR1)

Address offset: 0x34

Reset value: 0x0000 0000

|                                   |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|-----------------------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 31                                | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |
| CCR1[31:16] (depending on timers) |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro                             | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |
| 15                                | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR1[15:0]                        |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro                             | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 31:16 **CCR1[31:16]**: High Capture/Compare 1 value (on TIM2 and TIM5).

Bits 15:0 **CCR1[15:0]**: Low Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx\_CCR1 register is read-only and cannot be programmed.

### 18.4.14 TIMx capture/compare register 2 (TIMx\_CCR2)

Address offset: 0x38

Reset value: 0x0000 0000

|                                   |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|-----------------------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 31                                | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |
| CCR2[31:16] (depending on timers) |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro                             | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |
| 15                                | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR2[15:0]                        |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro                             | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 31:16 **CCR2[31:16]**: High Capture/Compare 2 value (on TIM2 and TIM5).

Bits 15:0 **CCR2[15:0]**: Low Capture/Compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx\_CCR2 register is read-only and cannot be programmed.

### 18.4.15 TIMx capture/compare register 3 (TIMx\_CCR3)

Address offset: 0x3C

Reset value: 0x0000 0000

|                                   |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|-----------------------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 31                                | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |
| CCR3[31:16] (depending on timers) |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro                             | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |
| 15                                | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR3[15:0]                        |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro                             | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 31:16 **CCR3[31:16]**: High Capture/Compare 3 value (on TIM2 and TIM5).

Bits 15:0 **CCR3[15:0]**: Low Capture/Compare value

**If channel CC3 is configured as output:**

CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC3 output.

**If channel CC3 is configured as input:**

CCR3 is the counter value transferred by the last input capture 3 event (IC3). The TIMx\_CCR3 register is read-only and cannot be programmed.

### 18.4.16 TIMx capture/compare register 4 (TIMx\_CCR4)

Address offset: 0x40

Reset value: 0x0000 0000

|                                   |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|-----------------------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 31                                | 30    | 29    | 28    | 27    | 26    | 25    | 24    | 23    | 22    | 21    | 20    | 19    | 18    | 17    | 16    |
| CCR4[31:16] (depending on timers) |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro                             | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |
| 15                                | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR4[15:0]                        |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro                             | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 31:16 **CCR4[31:16]**: High Capture/Compare 4 value (on TIM2 and TIM5).

Bits 15:0 **CCR4[15:0]**: Low Capture/Compare value

1. if CC4 channel is configured as output (CC4S bits):  
CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.  
The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signalled on OC4 output.
2. if CC4 channel is configured as input (CC4S bits in TIMx\_CCMR4 register):  
CCR4 is the counter value transferred by the last input capture 4 event (IC4). The TIMx\_CCR4 register is read-only and cannot be programmed.

### 18.4.17 TIMx DMA control register (TIMx\_DCR)

Address offset: 0x48

Reset value: 0x0000

| 15       | 14 | 13 | 12       | 11 | 10 | 9  | 8  | 7        | 6 | 5 | 4        | 3  | 2  | 1  | 0  |
|----------|----|----|----------|----|----|----|----|----------|---|---|----------|----|----|----|----|
| Reserved |    |    | DBL[4:0] |    |    |    |    | Reserved |   |   | DBA[4:0] |    |    |    |    |
|          |    |    | rw       | rw | rw | rw | rw |          |   |   | rw       | rw | rw | rw | rw |

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the number of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx\_DMAR address).

00000: 1 transfer,  
00001: 2 transfers,  
00010: 3 transfers,  
...  
10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx\_DMAR address). DBA is defined as an offset starting from the address of the TIMx\_CR1 register.

Example:

00000: TIMx\_CR1,  
00001: TIMx\_CR2,  
00010: TIMx\_SMCR,  
...

**Example:** Let us consider the following transfer: DBL = 7 transfers & DBA = TIMx\_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx\_CR1 address.

**18.4.18 TIMx DMA address for full transfer (TIMx\_DMAR)**

Address offset: 0x4C

Reset value: 0x0000

|            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DMAB[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW         | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **DMAB[15:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address  
 $(\text{TIMx\_CR1 address}) + (\text{DBA} + \text{DMA index}) \times 4$

where TIMx\_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx\_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx\_DCR).

**Example of how to use the DMA burst feature**

In this example the timer DMA burst feature is used to update the contents of the CCRx registers ( $x = 2, 3, 4$ ) with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
  - DMA channel peripheral address is the DMAR register address
  - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
  - Number of data to transfer = 3 (See note below).
  - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:  
DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

**Note:** *This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.*

### 18.4.19 TIM2 option register (TIM2\_OR)

Address offset: 0x50

Reset value: 0x0000

|          |    |    |    |          |    |          |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----------|----|----------|---|---|---|---|---|---|---|---|---|

|          |    |    |    | rw       | rw |          |   |   |   |   |   |   |   |   |   |

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:10 **ITR1\_RMP**: Internal trigger 1 remap

Set and cleared by software.

00: TIM8\_TRGOUT

01: PTP trigger output is connected to TIM2\_ITR1

10: OTG FS SOF is connected to the TIM2\_ITR1 input

11: OTG HS SOF is connected to the TIM2\_ITR1 input

Bits 9:0 Reserved, must be kept at reset value.

### 18.4.20 TIM5 option register (TIM5\_OR)

Address offset: 0x50

Reset value: 0x0000

|          |    |    |    |    |    |   |   |         |    |          |   |   |   |   |   |
|----------|----|----|----|----|----|---|---|---------|----|----------|---|---|---|---|---|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7       | 6  | 5        | 4 | 3 | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |   |   | TI4_RMP |    | Reserved |   |   |   |   |   |
|          |    |    |    |    |    |   |   | rw      | rw |          |   |   |   |   |   |

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 **TI4\_RMP**: Timer Input 4 remap

Set and cleared by software.

00: TIM5 Channel4 is connected to the GPIO: Refer to the Alternate function mapping table in the datasheets.

01: the LSI internal clock is connected to the TIM5\_CH4 input for calibration purposes

10: the LSE internal clock is connected to the TIM5\_CH4 input for calibration purposes

11: the RTC wakeup interrupt is connected to TIM5\_CH4 input for calibration purposes.

Wakeup interrupt should be enabled.

Bits 5:0 Reserved, must be kept at reset value.

## 18.4.21 TIMx register map

TIMx registers are mapped as described in the table below:

Table 100. TIM2 to TIM5 register map and reset values

| Offset | Register                          | 31                                                               | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14        | 13            | 12                  | 11            | 10        | 9             | 8                   | 7             | 6             | 5        | 4        | 3     | 2             | 1        | 0    |      |   |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 19 General-purpose timers (TIM9 to TIM14)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 19.1 TIM9 to TIM14 introduction

The TIM9 to TIM14 general-purpose timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM9 to TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in [Section 19.3.12](#).

### 19.2 TIM9 to TIM14 main features

#### 19.2.1 TIM9/TIM12 main features

The features of the TIM9 to TIM14 general-purpose timers include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization or count by internal trigger)
  - Input capture
  - Output compare

Figure 180. General-purpose timer block diagram (TIM9 and TIM12)

## 19.2.2 TIM10/TIM11 and TIM13/TIM14 main features

The features of general-purpose timers TIM10/TIM11 and TIM13/TIM14 include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare

Figure 181. General-purpose timer block diagram (TIM10/11/13/14)

## 19.3 TIM9 to TIM14 functional description

### 19.3.1 Time-base unit

The main block of the timer is a 16-bit counter with its related auto-reload register. The counter counts up.

The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC)
- Auto-reload register (TIMx\_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx\_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in TIMx\_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx\_CR1 register.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 182* and *Figure 183* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 182. Counter timing diagram with prescaler division change from 1 to 2

Figure 183. Counter timing diagram with prescaler division change from 1 to 4

## 19.3.2 Counter modes

### Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller on TIM9 and TIM12) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx\_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx\_SR register) is set (depending on the URS bit):

- The auto-reload shadow register is updated with the preload value (TIMx\_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx\_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR=0x36.

**Figure 184. Counter timing diagram, internal clock divided by 1**

**Figure 188. Counter timing diagram, update event when ARPE=0 (TIMx\_ARR not preloaded)**

**Figure 189. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)**

### 19.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK\_INT)
- External clock mode1 (for **TIM9 and TIM12**): external input pin (Tlx)
- Internal trigger inputs (ITRx) (for **TIM9 and TIM12**): connecting the trigger output from another timer. Refer to [Using one timer as prescaler for another timer](#) for more details.

#### Internal clock source (CK\_INT)

The internal clock source is the default clock source for TIM10/TIM11 and TIM13/TIM14.

For TIM9 and TIM12, the internal clock source is selected when the slave mode controller is disabled (SMS='000'). The CEN bit in the TIMx\_CR1 register and the UG bit in the TIMx\_EGR register are then used as control bits and can be changed only by software (except for UG which remains cleared). As soon as the CEN bit is programmed to 1, the prescaler is clocked by the internal clock CK\_INT.

[Figure 190](#) shows the behavior of the control circuit and of the upcounter in normal mode, without prescaler.

**Figure 190. Control circuit in normal mode, internal clock divided by 1**

MS31085V2

#### External clock source mode 1 (TIM9 and TIM12)

This mode is selected when SMS='111' in the TIMx\_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 191. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx\_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx\_CCMR1 register (if no filter is needed, keep IC2F='0000').
3. Select the rising edge polarity by writing CC2P='0' and CC2NP='0' in the TIMx\_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS='111' in the TIMx\_SMCR register.
5. Select TI2 as the trigger input source by writing TS='110' in the TIMx\_SMCR register.
6. Enable the counter by writing CEN='1' in the TIMx\_CR1 register.

**Note:** The capture prescaler is not used for triggering, so no need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

Figure 192. Control circuit in external clock mode 1

### 19.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

[Figure 193](#) to [Figure 195](#) give an overview of a capture/compare channel.

The input stage samples the corresponding TIMx input to generate a filtered signal TIMx\_F. Then, an edge detector with polarity selection generates a signal (TIMx\_FPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

**Figure 193. Capture/compare channel (example: channel 1 input stage)**

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

cleared by software by writing it to '0' or by reading the captured data stored in the TIMx\_CCRx register. CCxOF is cleared when the user writes it to '0'.

The following example shows how to capture the counter value in TIMx\_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIMx\_CCR1 must be linked to the TI1 input, so write the CC1S bits to '01' in the TIMx\_CCMR1 register. As soon as CC1S becomes different from '00', the channel is configured in input mode and the TIMx\_CCR1 register becomes read-only.
2. Program the needed input filter duration with respect to the signal connected to the timer (by programming the ICxF bits in the TIMx\_CCMRx register if the input is one of the TIx inputs). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at  $f_{DTS}$  frequency). Then write IC1F bits to '0011' in the TIMx\_CCMR1 register.
3. Select the edge of the active transition on the TI1 channel by programming CC1P and CC1NP bits to '00' in the TIMx\_CCER register (rising edge in this case).
4. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to '00' in the TIMx\_CCMR1 register).
5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.
6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

*Note:* IC interrupt requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

### 19.3.6 PWM input mode (only for TIM9/12)

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, the user can measure the period (in TIMx\_CCR1 register) and the duty cycle (in TIMx\_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK\_INT frequency and prescaler value):

1. Select the active input for TIMx\_CCR1: write the CC1S bits to '01' in the TIMx\_CCMR1 register (TI1 selected).
2. Select the active polarity for TI1FP1 (used both for capture in TIMx\_CCR1 and counter clear): program the CC1P and CC1NP bits to '00' (active on rising edge).
3. Select the active input for TIMx\_CCR2: write the CC2S bits to '10' in the TIMx\_CCMR1 register (TI1 selected).
4. Select the active polarity for TI1FP2 (used for capture in TIMx\_CCR2): program the CC2P and CC2NP bits to '11' (active on falling edge).
5. Select the valid trigger input: write the TS bits to '101' in the TIMx\_SMCR register (TI1FP1 selected).
6. Configure the slave mode controller in reset mode: write the SMS bits to '100' in the TIMx\_SMCR register.
7. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx\_CCER register.

**Figure 196. PWM input mode timing**

1. The PWM input mode can be used only with the TIMx\_CH1/TIMx\_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 19.3.7 Forced output mode

In output mode (CCxS bits = '00' in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, the user just needs to write '101' in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP='0' (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to '100' in the TIMx\_CCMRx register.

Anyway, the comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

### 19.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx\_CCMRx register) and the output polarity (CCxP bit in the TIMx\_CCER register). The output pin can keep its level (OCxM='000'), be set active (OCxM='001'), be set inactive (OCxM='010') or can toggle (OCxM='011') on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIMx\_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx\_DIER register).

The TIMx\_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx\_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx\_ARR and TIMx\_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
  - Write OCxM = '011' to toggle OCx output pin when CNT matches CCRx
  - Write OCxPE = '0' to disable preload register
  - Write CCxP = '0' to select active high polarity
  - Write CCxE = '1' to enable the output
5. Enable the counter by setting the CEN bit in the TIMx\_CR1 register.

The TIMx\_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx\_CCRx shadow register is updated only at the next update event UEV). An example is given in [Figure 197](#).

**Figure 197. Output compare mode, toggle on OC1.**

### 19.3.9 PWM mode

Pulse Width Modulation mode allows the user to generate a signal with a frequency determined by the value of the TIMx\_ARR register and a duty cycle determined by the value of the TIMx\_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing '110' (PWM mode 1) or '111' (PWM mode 2) in the OCxM bits in the TIMx\_CCMRx register. Enable the corresponding preload register by setting the OCxPE bit in the TIMx\_CCMRx register, and eventually the auto-reload preload register by setting the ARPE bit in the TIMx\_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, the user has to initialize all the registers by setting the UG bit in the TIMx\_EGR register.

The OCx polarity is software programmable using the CCxP bit in the TIMx\_CCER register. It can be programmed as active high or active low. The OCx output is enabled by the CCxE bit in the TIMx\_CCER register. Refer to the TIMx\_CCERx register description for more details.

In PWM mode (1 or 2), TIMx\_CNT and TIMx\_CCRx are always compared to determine whether  $TIMx\_CNT \leq TIMx\_CCRx$ .

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

#### PWM edge-aligned mode

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as  $TIMx\_CNT < TIMx\_CCRx$  else it becomes low. If the compare value in

TIMx\_CCRx is greater than the auto-reload value (in TIMx\_ARR) then OCxREF is held at '1'. If the compare value is 0 then OCxRef is held at '0'. [Figure 198](#) shows some edge-aligned PWM waveforms in an example where TIMx\_ARR=8.

**Figure 198. Edge-aligned PWM waveforms (ARR=8)**

### 19.3.10 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. Select One-pulse mode by setting the OPM bit in the TIMx\_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be as follows:

$$CNT < CCRx \leq ARR \text{ (in particular, } 0 < CCRx)$$

Figure 199. Example of one pulse mode.

MS31099V1

For example the user may want to generate a positive pulse on OC1 with a length of  $t_{\text{PULSE}}$  and after a delay of  $t_{\text{DELAY}}$  as soon as a positive edge is detected on the TI2 input pin.

Use TI2FP2 as trigger 1:

1. Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx\_CCMR1 register.
2. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP = '0' in the TIMx\_CCER register.
3. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='110' in the TIMx\_SMCR register.
4. TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx\_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The  $t_{\text{DELAY}}$  is defined by the value written in the TIMx\_CCR1 register.
- The  $t_{\text{PULSE}}$  is defined by the difference between the auto-reload value and the compare value (TIMx\_ARR - TIMx\_CCR1).
- Let us say the user wants to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this enable PWM mode 2 by writing OC1M='111' in the TIMx\_CCMR1 register. The user can optionally enable the preload registers by writing OC1PE='1' in the TIMx\_CCMR1 register and ARPE in the TIMx\_CR1 register. In this case the user has to write the compare value in the TIMx\_CCR1 register, the auto-reload value in the TIMx\_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

The user only wants one pulse (Single mode), so write '1' in the OPM bit in the TIMx\_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx\_CR1 register is set to '0', so the Repetitive mode is selected.

**Particular case: OCx fast enable**

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay  $t_{\text{DELAY min}}$  we can get.

If the user wants to output a waveform with the minimum delay, set the OCxFE bit in the TIMx\_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

**19.3.11 TIM9/12 external trigger synchronization**

The TIM9/12 timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx\_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx\_ARR, TIMx\_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so there's no need to configure it. The CC1S bits select the input capture source only, CC1S = '01' in the TIMx\_CCMR1 register. Program CC1P and CC1NP to '00' in TIMx\_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS='100' in TIMx\_SMCR register. Select TI1 as the input source by writing TS='101' in TIMx\_SMCR register.
3. Start the counter by writing CEN='1' in the TIMx\_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx\_SR register) and an interrupt request can be sent if enabled (depending on the TIE bit in TIMx\_DIER register).

The following figure shows this behavior when the auto-reload register TIMx\_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

Figure 200. Control circuit in reset mode

### Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we don't need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so there's no need to configure it. The CC1S bits select the input capture source only, CC1S='01' in TIMx\_CCMR1 register. Program CC1P='1' and CC1NP='0' in TIMx\_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in gated mode by writing SMS='101' in TIMx\_SMCR register. Select TI1 as the input source by writing TS='101' in TIMx\_SMCR register.
3. Enable the counter by writing CEN='1' in the TIMx\_CR1 register (in gated mode, the counter doesn't start if CEN='0', whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx\_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Figure 201. Control circuit in gated mode****Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we don't need any filter, so we keep IC2F='0000'). The capture prescaler is not used for triggering, so there's no need to configure it. The CC2S bits are configured to select the input capture source only, CC2S='01' in TIMx\_CCMR1 register. Program CC2P='1' and CC2NP='0' in TIMx\_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in trigger mode by writing SMS='110' in TIMx\_SMCR register. Select TI2 as the input source by writing TS='110' in TIMx\_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 202. Control circuit in trigger mode**

### 19.3.12 Timer synchronization (TIM9/12)

The TIM timers are linked together internally for timer synchronization or chaining. Refer to [Section 18.3.15: Timer synchronization](#) for details.

*Note:* The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

### 19.3.13 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M4 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on DBG\_TIMx\_STOP configuration bit in DBG module. For more details, refer to [Section 38.16.2: Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C](#).

## 19.4 TIM9 and TIM12 registers

Refer to [Section 2.2](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

### 19.4.1 TIM9/12 control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9        | 8  | 7    | 6        | 5 | 4 | 3 | 2   | 1   | 0    |     |
|----------|----|----|----|----|----|----------|----|------|----------|---|---|---|-----|-----|------|-----|
| Reserved |    |    |    |    |    | CKD[1:0] |    | ARPE | Reserved |   |   |   | OPM | URS | UDIS | CEN |
|          |    |    |    |    |    | rw       | rw | rw   |          |   |   |   | rw  | rw  | rw   | rw  |

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **CKD**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (Tl<sub>x</sub>),

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 \times t_{CK\_INT}$

10:  $t_{DTS} = 4 \times t_{CK\_INT}$

11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered.

1: TIMx\_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped on the update event

1: Counter stops counting on the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt if enabled:

- Counter overflow
- Setting the UG bit

1: Only counter overflow generates an update interrupt if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable update event (UEV) generation.

0: UEV enabled. An UEV is generated by one of the following events:

- Counter overflow
- Setting the UG bit

Buffered registers are then loaded with their preload values.

1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCR<sub>x</sub>). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

CEN is cleared automatically in one-pulse mode, when an update event occurs.

### 19.4.2 TIM9/12 slave mode control register (TIMx\_SMCR)

Address offset: 0x08

Reset value: 0x0000

|          |    |    |    |    |    |   |   |     |         |    |    |    |      |          |    |  |
|----------|----|----|----|----|----|---|---|-----|---------|----|----|----|------|----------|----|--|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7   | 6       | 5  | 4  | 3  | 2    | 1        | 0  |  |
| Reserved |    |    |    |    |    |   |   | MSM | TS[2:0] |    |    |    | Res. | SMS[2:0] |    |  |
|          |    |    |    |    |    |   |   | rw  | rw      | rw | rw | rw |      | rw       | rw |  |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/Slave mode

0: No action

1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful in order to synchronize several timers on a single external event.

Bits 6:4 **TS**: Trigger selection

This bit field selects the trigger input to be used to synchronize the counter.

000: Internal Trigger 0 (ITR0)

001: Internal Trigger 1 (ITR1)

010: Internal Trigger 2 (ITR2)

011: Internal Trigger 3 (ITR3)

100: TI1 Edge Detector (TI1F\_ED)

101: Filtered Timer Input 1 (TI1FP1)

110: Filtered Timer Input 2 (TI2FP2)

111: Reserved.

See [Table 101](#) for more details on the meaning of ITRx for each timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS='000') to avoid wrong edge detections at the transition.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SMS**: Slave mode selection

When external signals are selected, the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input control register and Control register descriptions).

000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock

001: Reserved

010: Reserved

011: Reserved

100: Reset mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers

101: Gated mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Counter starts and stops are both controlled

110: Trigger mode - The counter starts on a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled

111: External clock mode 1 - Rising edges of the selected trigger (TRGI) clock the counter

*Note: The Gated mode must not be used if TI1F\_ED is selected as the trigger input (TS='100'). Indeed, TI1F\_ED outputs 1 pulse for each transition on TI1F, whereas the Gated mode checks the level of the trigger signal.*

*Note: The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

**Table 101. TIMx internal trigger connection**

| Slave TIM | ITR0 (TS = 000) | ITR1 (TS = 001) | ITR2 (TS = 010) | ITR3 (TS = 011) |
|-----------|-----------------|-----------------|-----------------|-----------------|
| TIM9      | TIM2_TRGO       | TIM3_TRGO       | TIM10_OC        | TIM11_OC        |
| TIM12     | TIM4_TRGO       | TIM5_TRGO       | TIM13_OC        | TIM14_OC        |

### 19.4.3 TIM9/12 Interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6   | 5   | 4 | 3 | 2     | 1     | 0   |
|----------|----|----|----|----|----|---|---|---|-----|-----|---|---|-------|-------|-----|
| Reserved |    |    |    |    |    |   |   |   | TIE | Res |   |   | CC2IE | CC1IE | UIE |
|          |    |    |    |    |    |   |   |   | rw  |     |   |   | rw    | rw    | rw  |

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TIE**: Trigger interrupt enable

0: Trigger interrupt disabled.

1: Trigger interrupt enabled.

Bit 5:3 Reserved, must be kept at reset value.

Bit 2 **CC2IE**: Capture/Compare 2 interrupt enable

0: CC2 interrupt disabled.

1: CC2 interrupt enabled.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable

0: CC1 interrupt disabled.

1: CC1 interrupt enabled.

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled.

1: Update interrupt enabled.

### 19.4.4 TIM9/12 status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10    | 9     | 8        | 7 | 6     | 5        | 4 | 3 | 2     | 1     | 0     |
|----------|----|----|----|----|-------|-------|----------|---|-------|----------|---|---|-------|-------|-------|
| Reserved |    |    |    |    | CC2OF | CC1OF | Reserved |   | TIF   | Reserved |   |   | CC2IF | CC1IF | UIF   |
|          |    |    |    |    | rc_w0 | rc_w0 |          |   | rc_w0 |          |   |   | rc_w0 | rc_w0 | rc_w0 |

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag  
refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.

0: No overcapture has been detected.

1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred.

1: Trigger interrupt pending.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag  
refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag

**If channel CC1 is configured as output:**

This flag is set by hardware when the counter matches the compare value. It is cleared by software.

0: No match.

1: The content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register. When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow.

**If channel CC1 is configured as input:**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred.

1: The counter value has been captured in TIMx\_CCR1 register (an edge has been detected on IC1 which matches the selected polarity).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow and if UDIS='0' in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS='0' and UDIS='0' in the TIMx\_CR1 register.
- When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS='0' and UDIS='0' in the TIMx\_CR1 register.

### 19.4.5 TIM9/12 event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6  | 5        | 4 | 3 | 2    | 1    | 0  |
|----------|----|----|----|----|----|---|---|---|----|----------|---|---|------|------|----|
| Reserved |    |    |    |    |    |   |   |   | TG | Reserved |   |   | CC2G | CC1G | UG |
|          |    |    |    |    |    |   |   |   | w  |          |   |   | w    | w    | w  |

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in the TIMx\_SR register. Related interrupt can occur if enabled

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **CC2G**: Capture/compare 2 generation

refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

the CC1IF flag is set, the corresponding interrupt is sent if enabled.

**If channel CC1 is configured as input:**

The current counter value is captured in the TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initializes the counter and generates an update of the registers. The prescaler counter is also cleared and the prescaler ratio is not affected. The counter is cleared.

### 19.4.6 TIM9/12 capture/compare mode register 1 (TIMx\_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes. For a given bit, OCxx describes its function when the channel is configured in output mode, ICxx describes its function when the channel is configured in input mode. Take care that the same bit can have different meanings for the input stage and the output stage.

| 15        | 14        | 13 | 12 | 11          | 10    | 9         | 8  | 7         | 6         | 5  | 4           | 3     | 2     | 1         | 0  |
|-----------|-----------|----|----|-------------|-------|-----------|----|-----------|-----------|----|-------------|-------|-------|-----------|----|
| Res.      | OC2M[2:0] |    |    | OC2PE       | OC2FE | CC2S[1:0] |    | Res.      | OC1M[2:0] |    |             | OC1PE | OC1FE | CC1S[1:0] |    |
| IC2F[3:0] |           |    |    | IC2PSC[1:0] |       |           |    | IC1F[3:0] |           |    | IC1PSC[1:0] |       |       |           |    |
| rw        | rw        | rw | rw | rw          | rw    | rw        | rw | rw        | rw        | rw | rw          | rw    | rw    | rw        | rw |

#### Output compare mode

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **OC2M[2:0]**: Output compare 2 mode

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **OC1M**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas the active levels of OC1 and OC1N depend on the CC1P and CC1NP bits, respectively.

000: Frozen - The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs. (this mode is used to generate a timing base).

001: Set channel 1 to active level on match. The OC1REF signal is forced high when the TIMx\_CNT counter matches the capture/compare register 1 (TIMx\_CCR1).

010: Set channel 1 to inactive level on match. The OC1REF signal is forced low when the TIMx\_CNT counter matches the capture/compare register 1 (TIMx\_CCR1).

011: Toggle - OC1REF toggles when TIMx\_CNT=TIMx\_CCR1

100: Force inactive level - OC1REF is forced low

101: Force active level - OC1REF is forced high

110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx\_CNT < TIMx\_CCR1 else it is inactive. In downcounting, channel 1 is inactive (OC1REF=0) as long as TIMx\_CNT > TIMx\_CCR1, else it is active (OC1REF=1)

111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx\_CNT < TIMx\_CCR1 else it is active. In downcounting, channel 1 is active as long as TIMx\_CNT > TIMx\_CCR1 else it is inactive.

*Note: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from "frozen" mode to "PWM" mode.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken into account immediately

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded into the active register at each update event

*Note: The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in the TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.  
0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles

1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, IC2 is mapped on TI2

10: CC2 channel is configured as input, IC2 is mapped on TI1

11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx\_SMCR register)

*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx\_CCER).*

Bits 7:4 **IC1F**: Input capture 1 filter

This bitfield defines the frequency used to sample the TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on the CC1 input (IC1).

The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: CC1 channel is configured as input, IC1 is mapped on TI2

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

### 19.4.7 TIM9/12 capture/compare enable register (TIMx\_CCER)

Address offset: 0x20

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6    | 5    | 4    | 3     | 2    | 1    | 0    |
|----------|----|----|----|----|----|---|---|-------|------|------|------|-------|------|------|------|

|          |    |    |    |    |    |   |   | rw    |      | rw   | rw   | rw    |      | rw   | rw   |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 output Polarity  
refer to CC1NP description

Bits 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output Polarity  
refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable  
refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity  
CC1 channel configured as output: CC1NP must be kept cleared  
CC1 channel configured as input: CC1NP is used in conjunction with CC1P to define  
TI1FP1/TI2FP1 polarity (refer to CC1P description).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output:**

0: OC1 active high.

1: OC1 active low.

**CC1 channel configured as input:**

CC1NP/CC1P bits select TI1FP1 and TI2FP1 polarity for trigger or capture operations.

00: noninverted/rising edge

Circuit is sensitive to TIxFP1 rising edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode, encoder mode).

01: inverted/falling edge

Circuit is sensitive to TIxFP1 falling edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is inverted (trigger in gated mode, encoder mode).

10: reserved, do not use this configuration.

*Note: 11: noninverted/both edges*

*Circuit is sensitive to both TIxFP1 rising and falling edges (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode). This configuration must not be used for encoder mode.*

Bit 0 **CC1E**: Capture/Compare 1 output enable.

**CC1 channel configured as output:**

0: Off - OC1 is not active.

1: On - OC1 signal is output on the corresponding output pin.

**CC1 channel configured as input:**

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.

0: Capture disabled.

1: Capture enabled.

Table 102. Output control bit for standard OCx channels

| CCxE bit | OCx output state                      |
|----------|---------------------------------------|
| 0        | Output disabled (OCx='0', OCx_EN='0') |
| 1        | OCx=OCxREF + Polarity, OCx_EN='1'     |

*Note:* The states of the external I/O pins connected to the standard OCx channels depend on the state of the OCx channel and on the GPIO registers.

#### 19.4.8 TIM9/12 counter (TIMx\_CNT)

Address offset: 0x24

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CNT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **CNT[15:0]**: Counter value

#### 19.4.9 TIM9/12 prescaler (TIMx\_PSC)

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in "reset mode").

#### 19.4.10 TIM9/12 auto-reload register (TIMx\_ARR)

Address offset: 0x2C

Reset value: 0xFFFF

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rW        | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to the [Section 19.3.1: Time-base unit](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 19.4.11 TIM9/12 capture/compare register 1 (TIMx\_CCR1)

Address offset: 0x34

Reset value: 0x0000

|            |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 15         | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR1[15:0] |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro      | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded into the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (OC1PE bit). Else the preload value is copied into the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the TIMx\_CNT counter and signaled on the OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx\_CCR1 register is read-only and cannot be programmed.

### 19.4.12 TIM9/12 capture/compare register 2 (TIMx\_CCR2)

Address offset: 0x38

Reset value: 0x0000

|            |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
|------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 15         | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| CCR2[15:0] |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro      | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:**

CCR2 is the value to be loaded into the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR2 register (OC2PE bit). Else the preload value is copied into the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the TIMx\_CNT counter and signalled on the OC2 output.

**If channel CC2 is configured as input:**

CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx\_CCR2 register is read-only and cannot be programmed.

TIM9/12 registers are mapped as 16-bit addressable registers as described below. The reserved memory areas are highlighted in gray in the table.

[illegible]

Table 103. TIM9/12 register map and reset values (continued)

| Offset       | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15         | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------------|-------------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 0x38         | TIMx_CCR2   | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | CCR2[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|              | Reset value |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0          | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0x3C to 0x4C | Reserved    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 19.5 TIM10/11/13/14 registers

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

### 19.5.1 TIM10/11/13/14 control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

|          |    |    |    |    |    |          |    |      |          |   |   |   |     |     |      |     |
|----------|----|----|----|----|----|----------|----|------|----------|---|---|---|-----|-----|------|-----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9        | 8  | 7    | 6        | 5 | 4 | 3 | 2   | 1   | 0    |     |
| Reserved |    |    |    |    |    | CKD[1:0] |    | ARPE | Reserved |   |   |   | OPM | URS | UDIS | CEN |
|          |    |    |    |    |    | rw       | rw | rw   |          |   |   |   | rw  | rw  | rw   | rw  |

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **CKD**: Clock division

This bit-field indicates the division ratio between the timer clock (CK\_INT) frequency and sampling clock used by the digital filters (Tl<sub>x</sub>),

00:  $t_{DTS} = t_{CK\_INT}$

01:  $t_{DTS} = 2 \times t_{CK\_INT}$

10:  $t_{DTS} = 4 \times t_{CK\_INT}$

11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered

1: TIMx\_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped on the update event

1: Counter stops counting on the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the update interrupt (UEV) sources.

0: Any of the following events generate an UEV if enabled:

- Counter overflow
- Setting the UG bit

1: Only counter overflow generates an UEV if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable update interrupt (UEV) event generation.

0: UEV enabled. An UEV is generated by one of the following events:

- Counter overflow
- Setting the UG bit.

Buffered registers are then loaded with their preload values.

1: UEV disabled. No UEV is generated, shadow registers keep their value (ARR, PSC, CCR<sub>x</sub>). The counter and the prescaler are reinitialized if the UG bit is set.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

### 19.5.2 TIM10/11/13/14 Interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

|          |    |    |    |    |    |   |   |   |   |   |   |   |   |       |     |
|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|-------|-----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1     | 0   |
| Reserved |    |    |    |    |    |   |   |   |   |   |   |   |   | CC1IE | UIE |
|          |    |    |    |    |    |   |   |   |   |   |   |   |   | rw    | rw  |

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CC1IE**: Capture/Compare 1 interrupt enable

0: CC1 interrupt disabled

1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled

1: Update interrupt enabled

### 19.5.3 TIM10/11/13/14 status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

|          |    |    |    |    |    |       |          |   |   |   |   |   |   |       |       |
|----------|----|----|----|----|----|-------|----------|---|---|---|---|---|---|-------|-------|
| 15       | 14 | 13 | 12 | 11 | 10 | 9     | 8        | 7 | 6 | 5 | 4 | 3 | 2 | 1     | 0     |
| Reserved |    |    |    |    |    | CC1OF | Reserved |   |   |   |   |   |   | CC1IF | UIF   |
|          |    |    |    |    |    | rc_w0 |          |   |   |   |   |   |   | rc_w0 | rc_w0 |

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.

0: No overcapture has been detected.

1: The counter value has been captured in TIMx\_CCR1 register while CC1IF flag was already set

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag

**If channel CC1 is configured as output:**

This flag is set by hardware when the counter matches the compare value. It is cleared by software.

0: No match.

1: The content of the counter TIMx\_CNT matches the content of the TIMx\_CCR1 register.

When the contents of TIMx\_CCR1 are greater than the contents of TIMx\_ARR, the CC1IF bit goes high on the counter overflow.

If channel CC1 is configured as input:

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx\_CCR1 register.

0: No input capture occurred.

1: The counter value has been captured in TIMx\_CCR1 register (an edge has been detected on IC1 which matches the selected polarity).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow and if UDIS='0' in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in TIMx\_EGR register, if URS='0' and UDIS='0' in the TIMx\_CR1 register.

### 19.5.4 TIM10/11/13/14 event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

|          |    |    |    |    |    |   |   |   |   |   |   |   |   |      |    |
|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|------|----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1    | 0  |
| Reserved |    |    |    |    |    |   |   |   |   |   |   |   |   | CC1G | UG |
|          |    |    |    |    |    |   |   |   |   |   |   |   |   | w    | w  |

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx\_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

### 19.5.5 TIM10/11/13/14 capture/compare mode register 1 (TIMx\_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So take care that the same bit can have a different meaning for the input stage and for the output stage.

|          |    |    |    |    |    |   |   |           |           |    |             |       |       |           |    |
|----------|----|----|----|----|----|---|---|-----------|-----------|----|-------------|-------|-------|-----------|----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7         | 6         | 5  | 4           | 3     | 2     | 1         | 0  |
| Reserved |    |    |    |    |    |   |   |           | OC1M[2:0] |    |             | OC1PE | OC1FE | CC1S[1:0] |    |
| Reserved |    |    |    |    |    |   |   | IC1F[3:0] |           |    | IC1PSC[1:0] |       |       |           |    |
|          |    |    |    |    |    |   |   | rw        | rw        | rw | rw          | rw    | rw    | rw        | rw |

## Output compare mode

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **OC1M**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas OC1 active level depends on CC1P bit.

000: Frozen. The comparison between the output compare register TIMx\_CCR1 and the counter TIMx\_CNT has no effect on the outputs.

001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx\_CNT matches the capture/compare register 1 (TIMx\_CCR1).

011: Toggle - OC1REF toggles when TIMx\_CNT = TIMx\_CCR1.

100: Force inactive level - OC1REF is forced low.

101: Force active level - OC1REF is forced high.

110: PWM mode 1 - Channel 1 is active as long as TIMx\_CNT < TIMx\_CCR1 else inactive.

111: PWM mode 2 - Channel 1 is inactive as long as TIMx\_CNT < TIMx\_CCR1 else active.

*Note: In PWM mode 1 or 2, the OCREF level changes when the result of the comparison changes or when the output compare mode switches from frozen to PWM mode.*

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIMx\_CCR1 disabled. TIMx\_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx\_CCR1 enabled. Read/Write operations access the preload register. TIMx\_CCR1 preload value is loaded in the active register at each update event.

*Note: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx\_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.  
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. OC is then set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC1 channel is configured as output.

01: CC1 channel is configured as input, IC1 is mapped on TI1.

10:

11:

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

## Input capture mode

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:4 **IC1F**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at  $f_{DTS}$

0001:  $f_{SAMPLING}=f_{CK\_INT}$ , N=2

0010:  $f_{SAMPLING}=f_{CK\_INT}$ , N=4

0011:  $f_{SAMPLING}=f_{CK\_INT}$ , N=8

0100:  $f_{SAMPLING}=f_{DTS}/2$ , N=6

0101:  $f_{SAMPLING}=f_{DTS}/2$ , N=8

0110:  $f_{SAMPLING}=f_{DTS}/4$ , N=6

0111:  $f_{SAMPLING}=f_{DTS}/4$ , N=8

1000:  $f_{SAMPLING}=f_{DTS}/8$ , N=6

1001:  $f_{SAMPLING}=f_{DTS}/8$ , N=8

1010:  $f_{SAMPLING}=f_{DTS}/16$ , N=5

1011:  $f_{SAMPLING}=f_{DTS}/16$ , N=6

1100:  $f_{SAMPLING}=f_{DTS}/16$ , N=8

1101:  $f_{SAMPLING}=f_{DTS}/32$ , N=5

1110:  $f_{SAMPLING}=f_{DTS}/32$ , N=6

1111:  $f_{SAMPLING}=f_{DTS}/32$ , N=8

Bits 3:2 **IC1PSC**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1).

The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

10: Reserved

11: Reserved

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx\_CCER).*

### 19.5.6 TIM10/11/13/14 capture/compare enable register (TIMx\_CCER)

Address offset: 0x20

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3     | 2    | 1    | 0    |
|----------|----|----|----|----|----|---|---|---|---|---|---|-------|------|------|------|
| Reserved |    |    |    |    |    |   |   |   |   |   |   | CC1NP | Res. | CC1P | CC1E |
|          |    |    |    |    |    |   |   |   |   |   |   | rw    |      | rw   | rw   |

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity.

CC1 channel configured as output: CC1NP must be kept cleared.

CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define TI1FP1 polarity (refer to CC1P description).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/Compare 1 output Polarity.

**CC1 channel configured as output:**

0: OC1 active high

1: OC1 active low

**CC1 channel configured as input:**

The CC1P bit selects TI1FP1 and TI2FP1 polarity for trigger or capture operations.

00: noninverted/rising edge

Circuit is sensitive to TI1FP1 rising edge (capture mode), TI1FP1 is not inverted.

01: inverted/falling edge

Circuit is sensitive to TI1FP1 falling edge (capture mode), TI1FP1 is inverted.

10: reserved, do not use this configuration.

11: noninverted/both edges

Circuit is sensitive to both TI1FP1 rising and falling edges (capture mode), TI1FP1 is not inverted.

Bit 0 **CC1E**: Capture/Compare 1 output enable.

**CC1 channel configured as output:**

0: Off - OC1 is not active

1: On - OC1 signal is output on the corresponding output pin

**CC1 channel configured as input:**

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx\_CCR1) or not.

0: Capture disabled

1: Capture enabled

**Table 104. Output control bit for standard OCx channels**

| CCxE bit | OCx output state                      |
|----------|---------------------------------------|
| 0        | Output Disabled (OCx='0', OCx_EN='0') |
| 1        | OCx=OCxREF + Polarity, OCx_EN='1'     |

*Note:* The state of the external I/O pins connected to the standard OCx channels depends on the OCx channel state and the GPIO registers.

**19.5.7 TIM10/11/13/14 counter (TIMx\_CNT)**

Address offset: 0x24

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| CNT[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **CNT[15:0]**: Counter value**19.5.8 TIM10/11/13/14 prescaler (TIMx\_PSC)**

Address offset: 0x28

Reset value: 0x0000

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]**: Prescaler valueThe counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in "reset mode").

**19.5.9 TIM10/11/13/14 auto-reload register (TIMx\_ARR)**

Address offset: 0x2C

Reset value: 0xFFFF

|           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to [Section 19.3.1: Time-base unit](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

### 19.5.10 TIM10/11/13/14 capture/compare register 1 (TIMx\_CCR1)

Address offset: 0x34

Reset value: 0x0000

| 15         | 14    | 13    | 12    | 11    | 10    | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| CCR1[15:0] |       |       |       |       |       |       |       |       |       |       |       |       |       |       |       |
| rw/ro      | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro | rw/ro |

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx\_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx\_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1). The TIMx\_CCR1 register is read-only and cannot be programmed.

### 19.5.11 TIM11 option register 1 (TIM11\_OR)

Address offset: 0x50

Reset value: 0x0000

| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1            | 0 |
|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|--------------|---|
| Reserved |    |    |    |    |    |   |   |   |   |   |   |   |   | TI1_RMP[1:0] |   |
|          |    |    |    |    |    |   |   |   |   |   |   |   |   | rw           |   |

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 **TI1\_RMP[1:0]**: TIM11 Input 1 remapping capability

Set and cleared by software.

00,01,11: TIM11 Channel1 is connected to the GPIO (refer to the Alternate function mapping table in the datasheets).

10: HSE\_RTC clock (HSE divided by programmable prescaler) is connected to the TIM11\_CH1 input for measurement purposes

TIMx registers are mapped as 16-bit addressable registers as described in the table below.

| Offset          | Register                             | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17         | 16 | 15 | 14 | 13 | 12 | 11        | 10 | 9             | 8                   | 7             | 6            | 5     | 4             | 3    | 2    | 1 | 0 |

Refer to [Section 3.3: Memory map](#) for the register boundary addresses.

## 20 Basic timers (TIM6 and TIM7)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 20.1 TIM6 and TIM7 introduction

The basic timers TIM6 and TIM7 consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time-base generation but they are also specifically used to drive the digital-to-analog converter (DAC). In fact, the timers are internally connected to the DAC and are able to drive it through their trigger outputs.

The timers are completely independent, and do not share any resources.

### 20.2 TIM6 and TIM7 main features

Basic timer (TIM6 and TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65536
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

**Figure 203. Basic timer block diagram**

## 20.3 TIM6 and TIM7 functional description

### 20.3.1 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx\_CNT)
- Prescaler register (TIMx\_PSC)
- Auto-Reload register (TIMx\_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx\_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx\_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK\_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx\_CR1 register is set.

Note that the actual counter enable signal CNT\_EN is set 1 clock cycle after CEN.

#### Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx\_PSC register). It can be changed on the fly as the TIMx\_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

[Figure 204](#) and [Figure 205](#) give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 204. Counter timing diagram with prescaler division change from 1 to 2

Figure 205. Counter timing diagram with prescaler division change from 1 to 4

### 20.3.2 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx\_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx\_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx\_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx\_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx\_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx\_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx\_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx\_ARR = 0x36.

**Figure 206. Counter timing diagram, internal clock divided by 1**

Figure 207. Counter timing diagram, internal clock divided by 2

Figure 208. Counter timing diagram, internal clock divided by 4

Figure 209. Counter timing diagram, internal clock divided by N

**Figure 210. Counter timing diagram, update event when ARPE=0 (TIMx\_ARR not preloaded)**

**Figure 211. Counter timing diagram, update event when ARPE=1 (TIMx\_ARR preloaded)**

### 20.3.3 Clock source

The counter clock is provided by the Internal clock (CK\_INT) source.

The CEN (in the TIMx\_CR1 register) and UG bits (in the TIMx\_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK\_INT.

*Figure 212* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 212. Control circuit in normal mode, internal clock divided by 1

### 20.3.4 Debug mode

When the microcontroller enters the debug mode (Cortex<sup>®</sup>-M4 with FPU core - halted), the TIMx counter either continues to work normally or stops, depending on the DBG\_TIMx\_STOP configuration bit in the DBG module. For more details, refer to [Section 38.16.2: Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C](#).

## 20.4 TIM6 and TIM7 registers

Refer to [Section 2.2](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

### 20.4.1 TIM6 and TIM7 control register 1 (TIMx\_CR1)

Address offset: 0x00

Reset value: 0x0000

|          |    |    |    |    |    |   |   |      |          |   |   |   |     |     |      |     |
|----------|----|----|----|----|----|---|---|------|----------|---|---|---|-----|-----|------|-----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7    | 6        | 5 | 4 | 3 | 2   | 1   | 0    |     |
| Reserved |    |    |    |    |    |   |   | ARPE | Reserved |   |   |   | OPM | URS | UDIS | CEN |
|          |    |    |    |    |    |   |   | rw   |          |   |   |   | rw  | rw  | rw   | rw  |

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx\_ARR register is not buffered.

1: TIMx\_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event

1: Counter stops counting at the next update event (clearing the CEN bit).

**Bit 2 URS:** Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

**Bit 1 UDIS:** Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

**Bit 0 CEN:** Counter enable

0: Counter disabled

1: Counter enabled

*Note: Gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

## 20.4.2 TIM6 and TIM7 control register 2 (TIMx\_CR2)

Address offset: 0x04

Reset value: 0x0000

|          |    |    |    |    |    |   |   |   |          |    |    |          |   |   |   |
|----------|----|----|----|----|----|---|---|---|----------|----|----|----------|---|---|---|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6        | 5  | 4  | 3        | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |   |   |   | MMS[2:0] |    |    | Reserved |   |   |   |
|          |    |    |    |    |    |   |   |   | rw       | rw | rw |          |   |   |   |

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx\_EGR register is used as a trigger output (TRGO). If reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT\_EN, is used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in the TIMx\_SMCR register).

010: **Update** - The update event is selected as a trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

*Note: The clock of the slave timer and ADC must be enabled prior to receiving events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bits 3:0 Reserved, must be kept at reset value.

## 20.4.3 TIM6 and TIM7 DMA/Interrupt enable register (TIMx\_DIER)

Address offset: 0x0C

Reset value: 0x0000

|          |    |    |    |    |    |   |     |          |   |   |   |   |   |   |     |
|----------|----|----|----|----|----|---|-----|----------|---|---|---|---|---|---|-----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8   | 7        | 6 | 5 | 4 | 3 | 2 | 1 | 0   |
| Reserved |    |    |    |    |    |   | UDE | Reserved |   |   |   |   |   |   | UIE |
|          |    |    |    |    |    |   | rw  |          |   |   |   |   |   |   | rw  |

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **UDE**: Update DMA request enable

0: Update DMA request disabled.

1: Update DMA request enabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **UIE**: Update interrupt enable

0: Update interrupt disabled.

1: Update interrupt enabled.

#### 20.4.4 TIM6 and TIM7 status register (TIMx\_SR)

Address offset: 0x10

Reset value: 0x0000

|          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |       |
|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|-------|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
| Reserved |    |    |    |    |    |   |   |   |   |   |   |   |   |   | UIF   |
|          |    |    |    |    |    |   |   |   |   |   |   |   |   |   | rc_w0 |

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

- At overflow or underflow and if UDIS = 0 in the TIMx\_CR1 register.
- When CNT is reinitialized by software using the UG bit in the TIMx\_EGR register, if URS = 0 and UDIS = 0 in the TIMx\_CR1 register.

#### 20.4.5 TIM6 and TIM7 event generation register (TIMx\_EGR)

Address offset: 0x14

Reset value: 0x0000

|          |    |    |    |    |    |   |   |   |   |   |   |   |   |   |    |
|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|----|
| 15       | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0  |
| Reserved |    |    |    |    |    |   |   |   |   |   |   |   |   |   | UG |
|          |    |    |    |    |    |   |   |   |   |   |   |   |   |   | w  |

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

#### 20.4.6 TIM6 and TIM7 counter (TIMx\_CNT)

Address offset: 0x24

Reset value: 0x0000

|           |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| CNT[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| r/w       | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w | r/w |

Bits 15:0 **CNT[15:0]**: Counter value

## 20.4.7 TIM6 and TIM7 prescaler (TIMx\_PSC)

Address offset: 0x28

Reset value: 0x0000

| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| PSC[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency CK\_CNT is equal to  $f_{CK\_PSC} / (PSC[15:0] + 1)$ .

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx\_EGR register or through trigger controller when configured in “reset mode”).

## 20.4.8 TIM6 and TIM7 auto-reload register (TIMx\_ARR)

Address offset: 0x2C

Reset value: 0xFFFF

| 15        | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|-----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| ARR[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw        | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to [Section 20.3.1: Time-base unit](#) for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

## 20.4.9 TIM6 and TIM7 register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below.

**Table 106. TIM6 and TIM7 register map and reset values**

| Offset | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15        | 14 | 13 | 12 | 11 | 10 | 9 | 8        | 7        | 6   | 5        | 4    | 3   | 2 | 1   | 0 |
|--------|-------------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|----|---|----------|----------|-----|----------|------|-----|---|-----|---|
| 0x00   | TIMx_CR1    | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   | ARPE     | Reserved | OPM | URS      | UDIS | CEN |   |     |   |
|        | Reset value | 0        | 0  | 0  | 0  |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |          |          |     |          |      |     |   |     |   |
| 0x04   | TIMx_CR2    | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   | MMS[2:0] |          |     | Reserved |      |     |   |     |   |
|        | Reset value | 0        | 0  | 0  |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |          |          |     |          |      |     |   |     |   |
| 0x08   | Reserved    |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |          |          |     |          |      |     |   |     |   |
| 0x0C   | TIMx_DIER   | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   | UDE      | Reserved | UIE |          |      |     |   |     |   |
|        | Reset value | 0        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |          |          |     |          |      |     |   |     |   |
| 0x10   | TIMx_SR     | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |          |          |     |          |      |     |   | UIF |   |
|        | Reset value | 0        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |          |          |     |          |      |     |   |     |   |
| 0x14   | TIMx_EGR    | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |          |          |     |          |      |     |   | UG  |   |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 21 Independent watchdog (IWDG)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 21.1 IWDG introduction

The devices have two embedded watchdog peripherals which offer a combination of high safety level, timing accuracy and flexibility of use. Both watchdog peripherals (Independent and Window) serve to detect and resolve malfunctions due to software failure, and to trigger system reset or an interrupt (window watchdog only) when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus stays active even if the main clock fails. The window watchdog (WWDG) clock is prescaled from the APB1 clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The IWDG is best suited to applications which require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. The WWDG is best suited to applications which require the watchdog to react within an accurate timing window. For further information on the window watchdog, refer to [Section 22 on page 713](#).

### 21.2 IWDG main features

- Free-running downcounter
- clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Reset (if watchdog activated) when the downcounter value of 0x000 is reached

### 21.3 IWDG functional description

[Figure 213](#) shows the functional blocks of the independent watchdog module.

When the independent watchdog is started by writing the value 0xCCCC in the Key register (IWDG\_KR), the counter starts counting down from the reset value of 0xFFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0xAAAA is written in the IWDG\_KR register, the IWDG\_RLR value is reloaded in the counter and the watchdog reset is prevented.

#### 21.3.1 Hardware watchdog

If the “Hardware watchdog” feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and will generate a reset unless the Key register is written by the software before the counter reaches end of count.

#### 21.3.2 Register access protection

Write access to the IWDG\_PR and IWDG\_RLR registers is protected. To modify them, first write the code 0x5555 in the IWDG\_KR register. A write access to this register with a

different value will break the sequence and register access will be protected again. This implies that it is the case of the reload operation (writing 0xAAAA).

A status register is available to indicate that an update of the prescaler or the down-counter reload value is on going.

### 21.3.3 Debug mode

When the microcontroller enters debug mode (Cortex®-M4 with FPU core halted), the IWDG counter either continues to work normally or stops, depending on DBG\_IWDG\_STOP configuration bit in DBG module. For more details, refer to [Section 38.16.2: Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C](#).

**Figure 213. Independent watchdog block diagram**

**Note:** The watchdog function is implemented in the  $V_{DD}$  voltage domain, still functional in Stop and Standby modes.

**Table 107. Min/max IWDG timeout period (in ms) at 32 kHz (LSI)<sup>(1)</sup>**

| Prescaler divider | PR[2:0] bits | Min timeout RL[11:0]= 0x000 | Max timeout RL[11:0]= 0xFFFF |
|-------------------|--------------|-----------------------------|------------------------------|
| /4                | 0            | 0.125                       | 512                          |
| /8                | 1            | 0.25                        | 1024                         |
| /16               | 2            | 0.5                         | 2048                         |
| /32               | 3            | 1                           | 4096                         |
| /64               | 4            | 2                           | 8192                         |
| /128              | 5            | 4                           | 16384                        |
| /256              | 6            | 8                           | 32768                        |

1. These timings are given for a 32 kHz clock but the microcontroller internal RC frequency can vary. Refer to the LSI oscillator characteristics table in the device datasheet for maximum and minimum values.

## 21.4 IWDG registers

Refer to [Section 2.2 on page 45](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by half-words (16 bits) or words (32 bits).

### 21.4.1 Key register (IWDG\_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15        | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | KEY[15:0] |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | w         | w  | w  | w  | w  | w  | w | w | w | w | w | w | w | w | w | w |

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **KEY[15:0]**: Key value (write only, read 0000h)

These bits must be written by software at regular intervals with the key value AAAAh, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 5555h to enable access to the IWDG\_PR and IWDG\_RLR registers (see [Section 21.3.2](#))

Writing the key value CCCCh starts the watchdog (except if the hardware watchdog option is selected)

### 21.4.2 Prescaler register (IWDG\_PR)

Address offset: 0x04

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |         |     |     |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---------|-----|-----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2       | 1   | 0   |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   | PR[2:0] |     |     |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   | r/w     | r/w | r/w |

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **PR[2:0]**: Prescaler divider

These bits are write access protected see [Section 21.3.2](#). They are written by software to select the prescaler divider feeding the counter clock. PVU bit of IWDG\_SR must be reset in order to be able to change the prescaler divider.

000: divider /4

001: divider /8

010: divider /16

011: divider /32

100: divider /64

101: divider /128

110: divider /256

111: divider /256

**Note:** Reading this register returns the prescaler value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the IWDG\_SR register is reset.

### 21.4.3 Reload register (IWDG\_RLR)

Address offset: 0x08

Reset value: 0x0000 0FFF (reset by Standby mode)

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |          |    |    |    |    |    |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11       | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RL[11:0] |    |    |    |    |    |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | rW       | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW | rW |

Bits 31:12 Reserved, must be kept at reset value.

Bits11:0 **RL[11:0]**: Watchdog counter reload value

These bits are write access protected see [Section 21.3.2](#). They are written by software to define the value to be loaded in the watchdog counter each time the value AAAAh is written in the IWDG\_KR register. The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to [Table 107](#).

The RVU bit in the IWDG\_SR register must be reset in order to be able to change the reload value.

*Note: Reading this register returns the reload value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on this register. For this reason the value read from this register is valid only when the RVU bit in the IWDG\_SR register is reset.*

### 21.4.4 Status register (IWDG\_SR)

Address offset: 0x0C

Reset value: 0x0000 0000 (not reset by Standby mode)

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |     |     |   |   |   |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|-----|-----|---|---|---|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4   | 3   | 2 | 1 | 0 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   | RVU | PVU |   |   |   |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   | r   | r   |   |   |   |

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **RVU**: Watchdog counter reload value update

This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the V<sub>DD</sub> voltage domain (takes up to 5 RC 40 kHz cycles).

Reload value can be updated only when RVU bit is reset.

Bit 0 **PVU**: Watchdog prescaler value update

This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the V<sub>DD</sub> voltage domain (takes up to 5 RC 40 kHz cycles).

Prescaler value can be updated only when PVU bit is reset.

*Note: If several reload values or prescaler values are used by application, it is mandatory to wait until RVU bit is reset before changing the reload value and to wait until PVU bit is reset before changing the prescaler value. However, after updating the prescaler and/or the reload value it is not necessary to wait until RVU or PVU is reset before continuing code execution (even in case of low-power mode entry, the write operation is taken into account and will complete)*

## 21.4.5 IWDG register map

The following table gives the IWDG register map and reset values.

**Table 108. IWDG register map and reset values**

| Offset | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15        | 14 | 13 | 12       | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3       | 2 | 1   | 0 |
|--------|-------------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----------|----|----|---|---|---|---|---|---|---------|---|-----|---|
| 0x00   | IWDG_KR     | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | KEY[15:0] |    |    |          |    |    |   |   |   |   |   |   |         |   |     |   |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0         | 0  | 0  | 0        | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0       | 0 | 0   | 0 |
| 0x04   | IWDG_PR     | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |          |    |    |   |   |   |   |   |   | PR[2:0] |   |     |   |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |          |    |    |   |   |   |   |   |   | 0       | 0 | 0   |   |
| 0x08   | IWDG_RLR    | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    | RL[11:0] |    |    |   |   |   |   |   |   |         |   |     |   |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    | 1        | 1  | 1  | 1 | 1 | 1 | 1 | 1 | 1 | 1       | 1 | 1   | 1 |
| 0x0C   | IWDG_SR     | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |          |    |    |   |   |   |   |   |   | RVU     |   | PVU |   |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |           |    |    |          |    |    |   |   |   |   |   |   | 0       | 0 |     |   |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 22 Window watchdog (WWDG)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 22.1 WWDG introduction

The window watchdog is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the contents of the downcounter before the T6 bit becomes cleared. An MCU reset is also generated if the 7-bit downcounter value (in the control register) is refreshed before the downcounter has reached the window register value. This implies that the counter must be refreshed in a limited window.

### 22.2 WWDG main features

- Programmable free-running downcounter
- Conditional reset
  - Reset (if watchdog activated) when the downcounter value becomes less than 0x40
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window (see [Figure 215](#))
- Early wakeup interrupt (EWI): triggered (if enabled and the watchdog activated) when the downcounter is equal to 0x40.

### 22.3 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG\_CR register) and when the 7-bit downcounter (T[6:0] bits) rolls over from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

Figure 214. Watchdog block diagram

The application program must write in the WWDG\_CR register at regular intervals during normal operation to prevent an MCU reset. This operation must occur only when the counter value is lower than the window register value. The value to be stored in the WWDG\_CR register must be between 0xFF and 0xC0.

### Enabling the watchdog

The watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG\_CR register, then it cannot be disabled again except by a reset.

### Controlling the downcounter

This downcounter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WWDG\_CR register (see [Figure 215](#)). The Configuration register (WWDG\_CFR) contains the high limit of the window: To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x3F. [Figure 215](#) describes the window watchdog process.

**Note:** The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

### Advanced watchdog interrupt feature

The Early Wakeup Interrupt (EWI) can be used if specific safety operations or data logging must be performed before the actual reset is generated. The EWI interrupt is enabled by setting the EWI bit in the WWDG\_CFR register. When the downcounter reaches the value 0x40, an EWI interrupt is generated and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case, the corresponding interrupt service routine (ISR) should reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The EWI interrupt is cleared by writing '0' to the EWIF bit in the WWDG\_SR register.

**Note:** When the EWI interrupt cannot be served, e.g. due to a system lock in a higher priority task, the WWDG reset will eventually be generated.

## 22.4 How to program the watchdog timeout

**Warning:** When writing to the WWDG\_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.

**Figure 215. Window watchdog timing diagram**

The formula to calculate the WWDG timeout value is given by:

$$t_{\text{WWDG}} = t_{\text{PCLK1}} \times 4096 \times 2^{\text{WDGTB}[1:0]} \times (T[5:0] + 1) \quad (\text{ms})$$

where:

$t_{\text{WWDG}}$ : WWDG timeout

$t_{\text{PCLK1}}$ : APB1 clock period measured in ms

4096: value corresponding to internal divider

As an example, let us assume APB1 frequency is equal to 24 MHz, WDGTB[1:0] is set to 3 and T[5:0] is set to 63:

$$t_{\text{WWDG}} = 1/24000 \times 4096 \times 2^3 \times (63 + 1) = 21.85\text{ms}$$

Refer to [Table 109](#) for the minimum and maximum values of the  $t_{\text{WWDG}}$ .

**Table 109. Minimum and maximum timeout values at 30 MHz ( $f_{\text{PCLK1}}$ )**

| Prescaler | WDGTB | Min timeout ( $\mu\text{s}$ )<br>T[5:0] = 0x00 | Max timeout (ms)<br>T[5:0] = 0x3F |
|-----------|-------|------------------------------------------------|-----------------------------------|
| 1         | 0     | 136.53                                         | 8.74                              |
| 2         | 1     | 273.07                                         | 17.48                             |
| 4         | 2     | 546.13                                         | 34.95                             |
| 8         | 3     | 1092.27                                        | 69.91                             |

## 22.5 Debug mode

When the microcontroller enters debug mode (Cortex<sup>®</sup>-M4 with FPU core halted), the WWDG counter either continues to work normally or stops, depending on DBG\_WWDG\_STOP configuration bit in DBG module. For more details, refer to [Section 38.16.2: Debug support for timers, watchdog, bxCAN and I<sup>2</sup>C](#).

## 22.6 WWDG registers

Refer to [Section 2.2 on page 45](#) for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by half-words (16 bits) or words (32 bits).

### 22.6.1 Control register (WWDG\_CR)

Address offset: 0x00

Reset value: 0x0000 007F

|          |    |    |    |    |    |    |    |      |        |    |    |    |    |    |    |
|----------|----|----|----|----|----|----|----|------|--------|----|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22     | 21 | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |    |    |      |        |    |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7    | 6      | 5  | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    |    |    | WDGA | T[6:0] |    |    |    |    |    |    |
|          |    |    |    |    |    |    |    | rs   | rw     |    |    |    |    |    |    |

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WDGA**: Activation bit

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

Bits 6:0 **T[6:0]**: 7-bit counter (MSB to LSB)

These bits contain the value of the watchdog counter. It is decremented every  $(4096 \times 2^{\text{WDGTB}[1:0]})$  PCLK1 cycles. A reset is produced when it rolls over from 0x40 to 0x3F (T6 becomes cleared).

## 22.6.2 Configuration register (WWDG\_CFR)

Address offset: 0x04

Reset value: 0x0000 007F

|          |    |    |    |    |    |     |    |            |    |        |    |    |    |    |    |
|----------|----|----|----|----|----|-----|----|------------|----|--------|----|----|----|----|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25  | 24 | 23         | 22 | 21     | 20 | 19 | 18 | 17 | 16 |
| Reserved |    |    |    |    |    |     |    |            |    |        |    |    |    |    |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9   | 8  | 7          | 6  | 5      | 4  | 3  | 2  | 1  | 0  |
| Reserved |    |    |    |    |    | EWI |    | WDGTB[1:0] |    | W[6:0] |    |    |    |    |    |
|          |    |    |    |    |    | rs  |    | rw         |    | rw     |    |    |    |    |    |

Bit 31:10 Reserved, must be kept at reset value.

Bit 9 **EWI**: Early wakeup interrupt

When set, an interrupt occurs whenever the counter reaches the value 0x40. This interrupt is only cleared by hardware after a reset.

Bits 8:7 **WDGTB[1:0]**: Timer base

The time base of the prescaler can be modified as follows:

00: CK Counter Clock (PCLK1 div 4096) div 1

01: CK Counter Clock (PCLK1 div 4096) div 2

10: CK Counter Clock (PCLK1 div 4096) div 4

11: CK Counter Clock (PCLK1 div 4096) div 8

Bits 6:0 **W[6:0]**: 7-bit window value

These bits contain the window value to be compared to the downcounter.

## 22.6.3 Status register (WWDG\_SR)

Address offset: 0x08

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17    | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |       |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1     | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    | EWIF  |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    |    | rc_w0 |    |

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **EWIF**: Early wakeup interrupt flag

This bit is set by hardware when the counter has reached the value 0x40. It must be cleared by software by writing '0'. A write of '1' has no effect. This bit is also set if the interrupt is not enabled.

## 22.6.4 WWDG register map

The following table gives the WWDG register map and reset values.

**Table 110. WWDG register map and reset values**

| Offset | Register    | 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8   | 7      | 6      | 5      | 4 | 3 | 2 | 1 | 0 |      |
|--------|-------------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|-----|--------|--------|--------|---|---|---|---|---|------|
| 0x00   | WWDG_CR     | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |     | WDGA   | T[6:0] |        |   |   |   |   |   |      |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |     | 0      | 1      | 1      | 1 | 1 | 1 | 1 | 1 |      |
| 0x04   | WWDG_CFR    | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   | EWI | WDGTB1 | WDGTB0 | W[6:0] |   |   |   |   |   |      |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   | 0   | 0      | 0      | 1      | 1 | 1 | 1 | 1 | 1 | 1    |
| 0x08   | WWDG_SR     | Reserved |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |     |        |        |        |   |   |   |   |   | EWIF |
|        | Reset value |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |     |        |        |        |   |   |   |   |   | 0    |

Refer to [Section 2.3: Memory map](#) for the register boundary addresses.

## 23 Cryptographic processor (CRYP)

This section applies to STM32F415/417xx and STM32F43xxx devices.

### 23.1 CRYP introduction

The cryptographic processor can be used to both encipher and decipher data using the DES, Triple-DES or AES (128, 192, or 256) algorithms. It is a fully compliant implementation of the following standards:

- The data encryption standard (DES) and Triple-DES (TDES) as defined by Federal Information Processing Standards Publication (FIPS PUB 46-3, 1999 October 25). It follows the American National Standards Institute (ANSI) X9.52 standard.
- The advanced encryption standard (AES) as defined by Federal Information Processing Standards Publication (FIPS PUB 197, 2001 November 26)

The CRYP processor performs data encryption and decryption using DES and TDES algorithms in Electronic codebook (ECB) or Cipher block chaining (CBC) mode.

The CRYP peripheral is a 32-bit AHB2 peripheral. It supports DMA transfer for incoming and processed data, and has input and output FIFOs (each 8 words deep).

### 23.2 CRYP main features

- Suitable for AES, DES and TDES enciphering and deciphering operations
- AES
  - Supports the ECB, CBC, CTR, CCM and GCM chaining algorithms (CCM and GCM are available on STM32F42xxx and STM32F43xxx only)
  - Supports 128-, 192- and 256-bit keys
  - 4 × 32-bit initialization vectors (IV) used in the CBC, CTR, CCM and GCM modes

**Table 111. Number of cycles required to process each 128-bit block (STM32F415/417xx)**

| Algorithm / Key size | ECB | CBC | CTR |
|----------------------|-----|-----|-----|
| 128b                 | 14  | 14  | 14  |
| 192b                 | 16  | 16  | 16  |
| 256b                 | 18  | 18  | 18  |

**Table 112. Number of cycles required to process each 128-bit block (STM32F43xxx)**

| Algorithm / Key size | ECB | CBC | CTR | GCM  |        |         |     | CCM  |        |         |     |
|----------------------|-----|-----|-----|------|--------|---------|-----|------|--------|---------|-----|
|                      |     |     |     | Init | Header | Payload | Tag | Init | Header | Payload | Tag |
| 128b                 | 14  | 14  | 14  | 24   | 10     | 14      | 14  | 12   | 14     | 25      | 14  |

**Table 112. Number of cycles required to process each 128-bit block  
(STM32F43xxx)**

|      |    |    |    |    |    |    |    |    |    |    |    |
|------|----|----|----|----|----|----|----|----|----|----|----|
| 192b | 16 | 16 | 16 | 28 | 10 | 16 | 16 | 14 | 16 | 29 | 16 |
| 256b | 18 | 18 | 18 | 32 | 10 | 18 | 18 | 16 | 18 | 33 | 18 |

- DES/TDES
  - Direct implementation of simple DES algorithms (a single key, K1, is used)
  - Supports the ECB and CBC chaining algorithms
  - Supports 64-, 128- and 192-bit keys (including parity)
  - 2 × 32-bit initialization vectors (IV) used in the CBC mode
  - 16 HCLK cycles to process one 64-bit block in DES
  - 48 HCLK cycles to process one 64-bit block in TDES
- Common to DES/TDES and AES
  - IN and OUT FIFO (each with an 8-word depth, a 32-bit width, corresponding to 4 DES blocks or 2 AES blocks)
  - Automatic data flow control with support of direct memory access (DMA) (using 2 channels, one for incoming data the other for processed data)
  - Data swapping logic to support 1-, 8-, 16- or 32-bit data

## 23.3 CRYP functional description

The cryptographic processor implements a Triple-DES (TDES, that also supports DES) core and an AES cryptographic core. [Section 23.3.1](#) and [Section 23.3.2](#) provide details on these cores.

Since the TDES and the AES algorithms use block ciphers, incomplete input data blocks have to be padded prior to encryption (extra bits should be appended to the trailing end of the data string). After decryption, the padding has to be discarded. The hardware does not manage the padding operation, the software has to handle it.

[Figure 216](#) shows the block diagram of the cryptographic processor.

**Figure 216. Block diagram (STM32F415/417xx)**

Figure 217. Block diagram (STM32F43xxx)

### 23.3.1 DES/TDES cryptographic core

The DES/Triple-DES cryptographic core consists of three components:

- The DES algorithm (DEA)
- Multiple keys (1 for the DES algorithm, 1 to 3 for the TDES algorithm)
- The initialization vector (used in the CBC mode)

The basic processing involved in the TDES is as follows: an input block is read in the DEA and encrypted using the first key, K1 (K0 is not used in TDES mode). The output is then decrypted using the second key, K2, and encrypted using the third key, K3. The key depends on the algorithm which is used:

- DES mode: Key = [K1]
- TDES mode: Key = [K3 K2 K1]

where  $Kx = [KxR \ KxL]$ , R = right, L = left

According to the mode implemented, the resultant output block is used to calculate the ciphertext.

Note that the outputs of the intermediate DEA stages is never revealed outside the cryptographic boundary.

The TDES allows three different keying options:

- Three independent keys  
The first option specifies that all the keys are independent, that is, K1, K2 and K3 are independent. FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this option as the Keying Option 1 and, to the TDES as 3-key TDES.
- Two independent keys  
The second option specifies that K1 and K2 are independent and K3 is equal to K1, that is, K1 and K2 are independent,  $K3 = K1$ . FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this second option as the Keying Option 2 and, to the TDES as 2-key TDES.
- Three equal keys  
The third option specifies that K1, K2 and K3 are equal, that is,  $K1 = K2 = K3$ . FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to the third option as the Keying Option 3. This “1-key” TDES is equivalent to single DES.

FIPS PUB 46-3 – 1999 (and ANSI X9.52-1998) provides a thorough explanation of the processing involved in the four operation modes supplied by the TDEA (TDES algorithm): TDES-ECB encryption, TDES-ECB decryption, TDES-CBC encryption and TDES-CBC decryption.

This reference manual only gives a brief explanation of each mode.

### DES and TDES Electronic codebook (DES/TDES-ECB) mode

- DES/TDES-ECB mode encryption  
*Figure 218* illustrates the encryption in DES and TDES Electronic codebook (DES/TDES-ECB) mode. A 64-bit plaintext data block (P) is used after bit/byte/half-word swapping (refer to [Section 23.3.3: Data type on page 739](#)) as the input block (I). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA where the DES is performed in the decrypt state using K2. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K3. The resultant 64-bit output block (O) is used, after bit/byte/half-word swapping, as ciphertext (C) and it is pushed into the OUT FIFO.
- DES/TDES-ECB mode decryption  
*Figure 219* illustrates the DES/TDES-ECB decryption. A 64-bit ciphertext block (C) is used, after bit/byte/half-word swapping, as the input block (I). The keying sequence is reversed compared to that used in the encryption process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K2. The new result is directly fed to the input of the DEA where the DES is performed in the decrypt state using K1. The resultant 64-bit output block (O), after bit/byte/half-word swapping, produces the plaintext (P).

Figure 219. DES/TDES-ECB mode decryption

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.

**DES and TDES Cipher block chaining (DES/TDES-CBC) mode**

- DES/TDES-CBC mode encryption

[Figure 220](#) illustrates the DES and Triple-DES Cipher block chaining (DES/TDES-CBC) mode encryption. This mode begins by dividing a plaintext message into 64-bit data blocks. In TCBC encryption, the first input block ( $I_1$ ), obtained after bit/byte/half-word swapping (refer to [Section 23.3.3: Data type on page 739](#)), is formed by exclusive-ORing the first plaintext data block ( $P_1$ ) with a 64-bit initialization vector IV ( $I_1 = IV \oplus P_1$ ). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA, which performs the DES in the decrypt state using K2. The output of this process is fed directly to the input of the DEA, which performs the DES in the encrypt state using K3. The resultant 64-bit output block ( $O_1$ ) is used directly as the ciphertext ( $C_1$ ), that is,  $C_1 = O_1$ . This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, ( $I_2$ ) = ( $C_1 \oplus P_2$ ). Note that  $I_2$  and  $P_2$  now refer to the second block. The second input block is processed through the TDEA to produce the second ciphertext block. This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted. If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application.

- DES/TDES-CBC mode decryption

In DES/TDES-CBC decryption (see [Figure 221](#)), the first ciphertext block ( $C_1$ ) is used directly as the input block ( $I_1$ ). The keying sequence is reversed compared to that used for the encrypt process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed directly to the input of the DEA where the DES is processed in the encrypt state using K2. This resulting value is directly fed to the input of the DEA where the DES is processed in the decrypt state using K1. The resulting output block is exclusive-ORed with the IV (which must be the same as that used during encryption) to produce the first plaintext block ( $P_1 = O_1 \oplus IV$ ). The second ciphertext block is then used as the next input block and is processed through the TDEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block ( $P_2 = O_2 \oplus C_1$ ). (Note that  $P_2$  and  $O_2$  refer to the second block of data.) The TCBC decryption process continues in this manner until the last complete ciphertext block has been decrypted. Ciphertext representing a partial data block must be decrypted in a manner specified for the application.

Figure 221. DES/TDES-CBC mode decryption

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: initialization vectors.

### 23.3.2 AES cryptographic core

The AES cryptographic core consists of three components:

- The AES algorithm (AEA: advanced encryption algorithm)
- Multiple keys
- Initialization vector(s) or Nonce

The AES utilizes keys of 3 possible lengths: 128, 192 or 256 bits and, depending on the operation mode used, zero or one 128-bit initialization vector (IV).

The basic processing involved in the AES is as follows: an input block of 128 bits is read from the input FIFO and sent to the AEA to be encrypted using the key (K0...3). The key format depends on the key size:

- If Key size = 128: Key = [K3 K2]
- If Key size = 192: Key = [K3 K2 K1]
- If Key size = 256: Key = [K3 K2 K1 K0]

where  $K_x = [K_{xR} \ K_{xL}]$ , R=right, L=left

According to the mode implemented, the resultant output block is used to calculate the ciphertext.

FIPS PUB 197 (November 26, 2001) provides a thorough explanation of the processing involved in the four operation modes supplied by the AES core: AES-ECB encryption, AES-

ECB decryption, AES-CBC encryption and AES-CBC decryption. This reference manual only gives a brief explanation of each mode.

### AES Electronic codebook (AES-ECB) mode

- AES-ECB mode encryption

[Figure 222](#) illustrates the AES Electronic codebook (AES-ECB) mode encryption.

In AES-ECB encryption, a 128-bit plaintext data block (P) is used after bit/byte/half-word swapping (refer to [Section 23.3.3: Data type on page 739](#)) as the input block (I). The input block is processed through the AEA in the encrypt state using the 128, 192 or 256-bit key. The resultant 128-bit output block (O) is used after bit/byte/half-word swapping as ciphertext (C). It is then pushed into the OUT FIFO.

- AES-ECB mode decryption

[Figure 223](#) illustrates the AES Electronic codebook (AES-ECB) mode encryption.

To perform an AES decryption in the ECB mode, the secret key has to be prepared (it is necessary to execute the complete key schedule for encryption) by collecting the last round key, and using it as the first round key for the decryption of the ciphertext. This preparation function is computed by the AES core. Refer to [Section 23.3.6: Procedure to perform an encryption or a decryption](#) for more details on how to prepare the key.

In AES-ECB decryption, a 128-bit ciphertext block (C) is used after bit/byte/half-word swapping as the input block (I). The keying sequence is reversed compared to that of the encryption process. The resultant 128-bit output block (O), after bit/byte or half-word swapping, produces the plaintext (P).

**Figure 222. AES-ECB mode encryption**

2. If Key size = 128 => Key = [K3 K2].  
 If Key size = 192 => Key = [K3 K2 K1].  
 If Key size = 256 => Key = [K3 K2 K1 K0].

### AES Cipher block chaining (AES-CBC) mode

- AES-CBC mode encryption

The AES Cipher block chaining (AES-CBC) mode decryption is shown on [Figure 224](#).

In AES-CBC encryption, the first input block ( $I_1$ ) obtained after bit/byte/half-word swapping (refer to [Section 23.3.3: Data type on page 739](#)) is formed by exclusive-ORing the first plaintext data block ( $P_1$ ) with a 128-bit initialization vector IV ( $I_1 = IV \oplus P_1$ ). The input block is processed through the AEA in the encrypt state using the 128-, 192- or 256-bit key ( $K_0...K_3$ ). The resultant 128-bit output block ( $O_1$ ) is used directly as ciphertext ( $C_1$ ), that is,  $C_1 = O_1$ . This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, ( $I_2 = C_1 \oplus P_2$ ). Note that  $I_2$  and  $P_2$  now refer to the second block. The second input block is processed through the AEA to produce the second ciphertext block. This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted. If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application.

In the CBC mode, like in the ECB mode, the secret key must be prepared to perform an AES decryption. Refer to [Section 23.3.6: Procedure to perform an encryption or a decryption on page 744](#) for more details on how to prepare the key.

- AES-CBC mode decryption

In AES-CBC decryption (see [Figure 225](#)), the first 128-bit ciphertext block ( $C_1$ ) is used directly as the input block ( $I_1$ ). The input block is processed through the AEA in the decrypt state using the 128-, 192- or 256-bit key. The resulting output block is exclusive-ORed with the 128-bit initialization vector IV (which must be the same as that used during encryption) to produce the first plaintext block ( $P_1 = O_1 \oplus IV$ ). The second ciphertext block is then used as the next input block and is processed through the AEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block ( $P_2 = O_2 \oplus C_1$ ). (Note that  $P_2$  and  $O_2$  refer to the second

block of data.) The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted. Ciphertext representing a partial data block must be decrypted in a manner specified for the application.

**Figure 224. AES-CBC mode encryption**

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.
2.  $IV_x = [IV_xR \ IV_xL]$ , R=right, L=left.
3. If Key size = 128 => Key = [K3 K2].  
If Key size = 192 => Key = [K3 K2 K1].  
If Key size = 256 => Key = [K3 K2 K1 K0].

### AES counter mode (AES-CTR) mode

The AES counter mode uses the AES block as a key stream generator. The generated keys are then XORed with the plaintext to obtain the cipher. For this reason, it makes no sense to speak of different CTR encryption/decryption, since the two operations are exactly the same.

In fact, given:

- Plaintext:  $P[0], P[1], \dots, P[n]$  (128 bits each)
- A key K to be used (the size does not matter)
- An initial counter block (call it ICB but it has the same functionality as the IV of CBC)

The cipher is computed as follows:

$C[i] = \text{enck}(iv[i]) \text{ xor } P[i]$ , where:

$iv[0] = \text{ICB}$  and  $iv[i+1] = \text{func}(iv[i])$ , where **func** is an update function applied to the previous iv block; **func** is basically an increment of one of the fields composing the iv block.

Given that the ICB for decryption is the same as the one for encryption, the key stream generated during decryption is the same as the one generated during encryption. Then, the ciphertext is XORed with the key stream in order to retrieve the original plaintext. The decryption operation therefore acts exactly in the same way as the encryption operation.

Figure 226 and Figure 227 illustrate AES-CTR encryption and decryption, respectively.

**Figure 226. AES-CTR mode encryption**

1. K: key; C: cipher text; I: input Block; o: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); Cs: cipher text after swapping (when decoding) or before swapping (when encoding); P: plain text; IV: Initialization vectors.

Figure 227. AES-CTR mode decryption

1. K: key; C: cipher text; I: input Block; o: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); Cs: cipher text after swapping (when decoding) or before swapping (when encoding); P: plain text; IV: Initialization vectors.

Figure 228 shows the structure of the IV block as defined by the standard [2]. It is composed of three distinct fields.

Figure 228. Initial counter block structure for the Counter mode

- Nonce is a 32-bit, single-use value. A new nonce should be assigned to each different communication.
- The initialization vector (IV) is a 64-bit value and the standard specifies that the encryptor must choose IV so as to ensure that a given value is used only once for a given key
- The counter is a 32-bit big-endian integer that is incremented each time a block has been encrypted. The initial value of the counter should be set to '1'.

The block increments the least significant 32 bits, while it leaves the other (most significant) 96 bits unchanged.

**AES Galois/counter mode (GCM)**

The AES Galois/counter mode (GCM) allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code or message integrity check). This algorithm is based on AES counter mode to ensure confidentiality. It uses a multiplier over a fixed finite field to generate the tag. An initialization vector is required at the beginning of the algorithm.

The message to be processed is split into 2 parts:

- The header (also known as additional authentication data): data which is authenticated but not protected (such as information for routing the packet)
- The payload (also known as plaintext or ciphertext): the message itself which is authenticated and encrypted.

*Note: The header must precede the payload and the two parts cannot be mixed together.*

The GCM standard requires to pass, at the end of the message, a specific 128-bit block composed of the size of the header (64 bits) and the size of the payload (64 bits). During the computation, the header blocks must be distinguished from the payload blocks.

In GCM mode, four steps are required to perform an encryption/decryption:

### 1. GCM init phase

During this first step, the HASH key is calculated and saved internally to be used for processing all the blocks. It is recommended to follow the sequence below:

- a) Make sure that the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP\_CR register.
- b) Select the GCM chaining mode by programming ALGOMODE bits to '01000' in CRYP\_CR.
- c) Configure GCM\_CCMPH bits to '00' in CRYP\_CR to start the GCM Init phase.
- d) Initialize the key registers (128, 192 and 256 bits) in CRYP\_KEYRx as well as the initialization vector (IV).
- e) Set CRYPEN bit to '1' to start the calculation of the HASH key.
- f) Wait for the CRYPEN bit to be cleared to '0' before moving on to the next phase.
- g) Set the CRYPEN bit to '1'.

### 2. GCM header phase

This step must be performed after the GCM Init phase:

- h) Set the GCM\_CCMPH bits to '01' in CRYP\_CR to indicate that the header phase has started.
- i) Write the header data. Three methods can be used:
  - Program the data by blocks of 32 bits into the CRYP\_DIN register, and use the IFNF flag to determine if the input FIFO can receive data. The size of the header must be a multiple of 128 bits (4 words).
  - Program the data into the CRYP\_DIN register by blocks of 8 words, and use the IFEM flag to determine if the input FIFO can receive data (IFEM='1'). The size of the header must be a multiple of 128 bits (4 words).
  - Use the DMA.
- j) Once all header data have been supplied, wait until the BUSY bit is cleared in the CRYP\_SR register.

### 3. GCM payload phase (encryption/decryption)

This step must be performed after the GCM header phase:

- k) Configure GCM\_CCMPH to '10' in the CRYP\_CR register.
- l) Select the algorithm direction (encryption or decryption) by using the ALGODIR bit in CRYP\_CR.
- m) Program the payload message into the CRYP\_DIN register, and use the IFNF flag to determine if the input FIFO can receive data. Alternatively, the data could be programmed into the CRYP\_DIN register by blocks of 8 words and the IFEM flag used to determine if the input FIFO can receive data (IFEM='1'). In parallel, the

OFNE/OFFU flag of the CRYP\_DOUT register can be monitored to check if the output FIFO is not empty.

- n) Repeat the previous step until all payload blocks have been encrypted or decrypted. Alternatively, DMA could be used.

#### 4. GCM final phase

This step generates the authentication tag:

- o) Configure GCM\_CCMPH[1:0] to '11' in CRYP\_CR.
- p) Write the input into the CRYP\_DIN register 4 times. The input must contain the number of bits in the header (64 bits) concatenated with the number of bits in the payload (64 bits).
- q) Wait till the OFNE flag (FIFO output not empty) is set to '1' in the CRYP\_SR register.
- r) Read the CRYP\_DOUT register 4 times: the output corresponds to the authentication tag.
- s) Disable the cryptographic processor (CRYPEN bit in CRYP\_CR = '0')

**Note:** *When a decryption is performed, it is not required to compute the key at the beginning. At the end of the decryption, the generated tag should be compared with the expected tag passed with the message. In addition, the ALGODIR bit (algorithm direction) must be set to '1'. No need to disable/enable CRYP processor when moving from header phase to tag phase.*

### AES Galois message authentication code (GMAC)

The cryptographic processor also supports GMAC to authenticate the plaintext. It uses the GCM algorithm and a multiplier over a fixed finite field to generate the corresponding tag.

An initialization vector is required at the beginning of the algorithm.

Actually, the GMAC algorithm corresponds to the GCM algorithm applied on a message composed of the header only. As a consequence, the payload phase is not required.

### AES combined cipher machine (CCM)

The CCM algorithm allows encrypting and authenticating the plaintext, as well as generating the corresponding ciphertext and tag (also known as message authentication code or message integrity check). This algorithm is based on AES counter mode to ensure confidentiality. It uses the AES CBC mode to generate a 128-bit tag.

The CCM standard (RFC 3610 Counter with CBC-MAC (CCM) dated September 2003) defines particular encoding rules for the first authentication block (called B0 in the standard). In particular, the first block includes flags, a nonce and the payload length expressed in bytes. The CCM standard specifies another format, called A or counter, for encryption/decryption. The counter is incremented during the payload phase and its 32 LSB bits are initialized to '1' during the tag generation (called A0 packet in the CCM standard).

**Note:** *The hardware does not perform the formatting operation of the B0 packet. It should be handled by the software.*

As for the GCM algorithm, the message to be processed is split into 2 parts:

- The header (also known as additional authentication data): data which is authenticated but not protected (such as information for routing the packet)
- The payload (also known as plaintext or ciphertext): the message itself which is authenticated and encrypted.

*Note: The header part must precede the payload and the two parts cannot be mixed together.*

In CCM mode, 4 steps are required to perform an encryption or decryption:

1. CCM init phase

In this first step, the B0 packet of the CCM message (1st packet) is programmed into the CRYP\_DIN register. During this phase, the CRYP\_DOUT register does not contain any output data.

The following sequence must be followed:

- a) Make sure that the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP\_CR register.
- b) Select the CCM chaining mode by programming the ALGOMODE bits to '01001' in the CRYP\_CR register.
- c) Configure the GCM\_CCMPH bits to '00' in CRYP\_CR to start the CCM Init phase.
- d) Initialize the key registers (128, 192 and 256 bits) in CRYP\_KEYRx as well as the initialization vector (IV).
- e) Set the CRYPEN bit to '1' in CRYP\_CR.
- f) Program the B0 packet into the input data register.
- g) Wait for the CRYPEN bit to be cleared before moving on to the next phase.
- h) Set CRYPEN to '1'.

2. CCM header phase

This step must be performed after the CCM Init phase. The sequence is identical for encryption and decryption.

During this phase, the CRYP\_DOUT register does not contain any output data.

This phase can be skipped if there is no additional authenticated data.

The following sequence must be followed:

- i) Set the GCM\_CCMPH bit to '01' in CRYP\_CR to indicate that the header phase has started.
- j) Three methods can be used:
  - Program the header data by blocks of 32 bits into the CRYP\_DIN register, and use the IFNF flag to determine if the input FIFO can receive data. The size of the header must be a multiple of 128 bits (4 words).
  - Program the header data into the CRYP\_DIN register by blocks of 8 words, and use the IFEM flag to determine if the input FIFO can receive data (IFEM='1'). The size of the header must be a multiple of 128 bits (4 words).
  - Use the DMA.

**Note:** *The first block B1 must be formatted with the header length. This task should be handled by software.*

- k) Once all header data have been supplied, wait until the BUSY flag is cleared.
- 3. CCM payload phase (encryption/decryption)
 

This step must be performed after the CCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP\_DOUT register.

The following sequence must be followed:

  - l) Configure GCM\_CCMPH bits to '10' in CRYP\_CR.
  - m) Select the algorithm direction (encryption or decryption) by using the ALGODIR bit in CRYP\_CR.
  - n) Program the payload message into the CRYP\_DIN register, and use the IFNF flag to determine if the input FIFO can receive data. Alternatively, the data could be programmed into the CRYP\_DIN register by blocks of 8 words and the IFEM flag used to determine if the input FIFO can receive data (IFEM='1'). In parallel, the OFNE/OFFU flag of the CRYP\_DOUT register can be monitored to check if the output FIFO is not empty.
  - o) Repeat the previous step until all payload blocks have been encrypted or decrypted. Alternatively, DMA could be used.
- 4. CCM final phase
 

This step generates the authentication tag. During this phase, the authentication tag of the message is generated and stored in the CRYP\_DOUT register.

  - p) Configure GCM\_CCMPH[1:0] bits to '11' in CRYP\_CR.
  - q) Load the A0 initialized counter, and program the 128-bit A0 value by writing 4 times 32 bits into the CRYP\_DIN register.
  - r) Wait till the OFNE flag (FIFO output not empty) is set to '1' in the CRYP\_SR register.
  - s) Read the CRYP\_DOUT register 4 times: the output corresponds to the encrypted authentication tag.
  - t) Disable the cryptographic processor (CRYPEN bit in CRYP\_CR = '0')

**Note:** *The hardware does not perform the formatting of the original B0 and B1 packets and the tag comparison between encryption and decryption. They have to be handled by software.*

*The cryptographic processor does not need to be disabled/enabled when moving from the header phase to the tag phase.*

AES cipher message authentication code (CMAC)

The CMAC algorithm allows authenticating the plaintext, and generating the corresponding tag. The CMAC sequence is identical to the CCM one, except that the payload phase is skipped.

### 23.3.3 Data type

Data enter the CRYP processor 32 bits (word) at a time as they are written into the CRYP\_DIN register. The principle of the DES is that streams of data are processed 64 bits by 64 bits and, for each 64-bit block, the bits are numbered from M1 to M64, with M1 the left-most bit and M64 the right-most bit of the block. The same principle is used for the AES, but with a 128-bit block size.

The system memory organization is little-endian: whatever the data type (bit, byte, 16-bit half-word, 32-bit word) used, the least-significant data occupy the lowest address locations. A bit, byte, or half-word swapping operation (depending on the kind of data to be encrypted) therefore has to be performed on the data read from the IN FIFO before they enter the CRYP processor. The same swapping operation should be performed on the CRYP data before they are written into the OUT FIFO. For example, the operation would be byte swapping for an ASCII text stream.

The kind of data to be processed is configured with the DATATYPE bitfield in the CRYP control register (CRYP\_CR).

Table 113. Data types

| DATATYPE in CRYP_CR | Swapping performed          | System memory data (plaintext or cypher)                                                                                                  |
|---------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 00b                 | No swapping                 | <p>Example: TDES block value <b>0xABCD77206973FE01</b> is represented in system memory as:</p> <p>TDES block size = 64bit = 2x 32 bit</p> |
| 01b                 | Half-word (16-bit) swapping | <p>Example: TDES block value <b>0xABCD77206973FE01</b> is represented in system memory as:</p> <p>TDES block size = 64bit = 2x 32 bit</p> |
| 10b                 | Byte (8-bit) swapping       | <p>Example: TDES block value <b>0xABCD77206973FE01</b> is represented in system memory as:</p> <p>TDES block size = 64bit = 2x 32 bit</p> |
| 11b                 | Bit swapping                | <p>TDES block value <b>0x4E6F772069732074</b> is represented in system memory as:</p> <p>TDES Bloc size = 64bit = 2x 32 bit</p>           |

Figure 229 shows how the 64-bit data block M1...64 is constructed from two consecutive 32-bit words popped off the IN FIFO by the CRYP processor, according to the DATATYPE value. The same schematic can easily be extended to form the 128-bit block for the AES

cryptographic algorithm (for the AES, the block length is four 32-bit words, but swapping only takes place at word level, so it is identical to the one described here for the TDES).

**Note:** *The same swapping is performed between the IN FIFO and the CRYP data block, and between the CRYP data block and the OUT FIFO.*

**Figure 229. 64-bit block construction according to DATATYPE**

### 23.3.4 Initialization vectors - CRYP\_IV0...1(L/R)

Initialization vectors are considered as two 64-bit data items. They therefore do not have the same data format and representation in system memory as plaintext or cypher data, and they are not affected by the DATATYPE value.

Initialization vectors are defined by two consecutive 32-bit words, CRYP\_IVL (left part, noted as bits IV1...32) and CRYP\_IVR (right part, noted as bits IV33...64).

During the DES or TDES CBC encryption, the CRYP\_IV0(L/R) bits are XORed with the 64-bit data block popped off the IN FIFO after swapping (according to the DATATYPE value), that is, with the M1...64 bits of the data block. When the output of the DEA3 block is available, it is copied back into the CRYP\_IV0(L/R) vector, and this new content is XORed with the next 64-bit data block popped off the IN FIFO, and so on.

During the DES or TDES CBC decryption, the CRYP\_IV0(L/R) bits are XORed with the 64-bit data block (that is, with the M1...64 bits) delivered by the TDEA1 block before swapping (according to the DATATYPE value), and pushed into the OUT FIFO. When the XORed result is swapped and pushed into the OUT FIFO, the CRYP\_IV0(L/R) value is replaced by the output of the IN FIFO, then the IN FIFO is popped, and a new 64-bit data block can be processed.

During the AES CBC encryption, the CRYP\_IV0...1(L/R) bits are XORed with the 128-bit data block popped off the IN FIFO after swapping (according to the DATATYPE value). When the output of the AES core is available, it is copied back into the CRYP\_IV0...1(L/R) vector, and this new content is XORed with the next 128-bit data block popped off the IN FIFO, and so on.

During the AES CBC decryption, the CRYP\_IV0...1(L/R) bits are XORed with the 128-bit data block delivered by the AES core before swapping (according to the DATATYPE value) and pushed into the OUT FIFO. When the XORed result is swapped and pushed into the OUT FIFO, the CRYP\_IV0...1(L/R) value is replaced by the output of the IN FIFO, then the IN FIFO is popped, and a new 128-bit data block can be processed.

During the AES CTR encryption or decryption, the CRYP\_IV0...1(L/R) bits are encrypted by the AES core. Then the result of the encryption is XORed with the 128-bit data block popped off the IN FIFO after swapping (according to the DATATYPE value). When the XORed result is swapped and pushed into the OUT FIFO, the counter part of the CRYP\_IV0...1(L/R) value (32 LSB) is incremented.

Any write operation to the CRYP\_IV0...1(L/R) registers when bit BUSY = 1b in the CRYP\_SR register is disregarded (CRYP\_IV0...1(L/R) register content not modified). Thus, you must check that bit BUSY = 0b before modifying initialization vectors.

**Figure 230. Initialization vectors use in the TDES-CBC encryption**

### 23.3.5 CRYP busy state

When there is enough data in the input FIFO (at least 2 words for the DES or TDES algorithm mode, 4 words for the AES algorithm mode) and enough free-space in the output FIFO (at least 2 (DES/TDES) or 4 (AES) word locations), and when the bit CRYPEN = 1 in the CRYP\_CR register, then the cryptographic processor automatically starts an encryption or decryption process (according to the value of the ALGODIR bit in the CRYP\_CR register).

This process takes 48 AHB2 clock cycles for the Triple-DES algorithm, 16 AHB2 clock cycles for the simple DES algorithm, and 14, 16 or 18 AHB2 clock cycles for the AES with key lengths of 128, 192 or 256 bits, respectively. During the whole process, the BUSY bit in the CRYP\_SR register is set to '1'. At the end of the process, two (DES/TDES) or four (AES) words are written by the CRYP Core into the output FIFO, and the BUSY bit is cleared. In

the CBC, CTR mode, the initialization vectors CRYPT\_IVx(L/R)R (x = 0..3) are updated as well.

A write operation to the key registers (CRYPT\_Kx(L/R)R, x = 0..3), the initialization registers (CRYPT\_IVx(L/R)R, x = 0..3), or to bits [9:2] in the CRYPT\_CR register are ignored when the cryptographic processor is busy (bit BUSY = 1b in the CRYPT\_SR register), and the registers are not modified. It is thus not possible to modify the configuration of the cryptographic processor while it is processing a block of data. It is however possible to clear the CRYPTEN bit while BUSY = 1, in which case the ongoing DES, TDES or AES processing is completed and the two/four word results are written into the output FIFO, and then, only then, the BUSY bit is cleared.

*Note: When a block is being processed in the DES or TDES mode, if the output FIFO becomes full and if the input FIFO contains at least one new block, then the new block is popped off the input FIFO and the BUSY bit remains high until there is enough space to store this new block into the output FIFO.*

### 23.3.6 Procedure to perform an encryption or a decryption

#### Initialization

1. Initialize the peripheral (the order of operations is not important except for the key preparation for AES-ECB or AES-CBC decryption. The key size and the key value must be entered before preparing the key and the algorithm must be configured once the key has been prepared):
  - a) Configure the key size (128-, 192- or 256-bit, in the AES only) with the KEYSIZE bits in the CRYPT\_CR register
  - b) Write the symmetric key into the CRYPT\_KxL/R registers (2 to 8 registers to be written depending on the algorithm)
  - c) Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE bits in the CRYPT\_CR register
  - d) In case of decryption in AES-ECB or AES-CBC, you must prepare the key: configure the key preparation mode by setting the ALGOMODE bits to '111' in the CRYPT\_CR register. Then write the CRYPTEN bit to '1': the BUSY bit is set. Wait until BUSY returns to 0 (CRYPTEN is automatically cleared as well): the key is prepared for decryption
  - e) Configure the algorithm and chaining (the DES/TDES in ECB/CBC, the AES in ECB/CBC/CTR/GCM/CCM) with the ALGOMODE bits in the CRYPT\_CR register
  - f) Configure the direction (encryption/decryption), with the ALGODIR bit in the CRYPT\_CR register
  - g) Write the initialization vectors into the CRYPT\_IVxL/R register (in CBC or CTR modes only)
2. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYPT\_CR register

#### Processing when the DMA is used to transfer the data from/to the memory

1. Configure the DMA controller to transfer the input data from the memory. The transfer length is the length of the message. As message padding is not managed by the peripheral, the message length must be an entire number of blocks. The data are transferred in burst mode. The burst length is 4 words in the AES and 2 or 4 words in

the DES/TDES. The DMA should be configured to set an interrupt on transfer completion of the output data to indicate that the processing is finished.

2. Enable the cryptographic processor by writing the CRYPEN bit to 1. Enable the DMA requests by setting the DIEN and DOEN bits in the CRYP\_DMACR register.
3. All the transfers and processing are managed by the DMA and the cryptographic processor. The DMA interrupt indicates that the processing is complete. Both FIFOs are normally empty and BUSY = 0.

#### **Processing when the data are transferred by the CPU during interrupts**

1. Enable the interrupts by setting the INIM and OUTIM bits in the CRYP\_IMSCR register.
2. Enable the cryptographic processor by setting the CRYPEN bit in the CRYP\_CR register.
3. In the interrupt managing the input data: load the input message into the IN FIFO. You can load 2 or 4 words at a time, or load data until the FIFO is full. When the last word of the message has been entered into the FIFO, disable the interrupt by clearing the INIM bit.
4. In the interrupt managing the output data: read the output message from the OUT FIFO. You can read 1 block (2 or 4 words) at a time or read data until the FIFO is empty. When the last word has been read, INIM=0, BUSY=0 and both FIFOs are empty (IFEM=1 and OFNE=0). You can disable the interrupt by clearing the OUTIM bit and, the peripheral by clearing the CRYPEN bit.

#### **Processing without using the DMA nor interrupts**

1. Enable the cryptographic processor by setting the CRYPEN bit in the CRYP\_CR register.
2. Write the first blocks in the input FIFO (2 to 8 words).
3. Repeat the following sequence until the complete message has been processed:
  - a) Wait for OFNE=1, then read the OUT-FIFO (1 block or until the FIFO is empty)
  - b) Wait for IFNF=1, then write the IN FIFO (1 block or until the FIFO is full)
4. At the end of the processing, BUSY=0 and both FIFOs are empty (IFEM=1 and OFNE=0). You can disable the peripheral by clearing the CRYPEN bit.

### **23.3.7 Context swapping**

If a context switching is needed because a new task launched by the OS requires this resource, the following tasks have to be performed for full context restoration (example when the DMA is used):

### Case of the AES and DES

1. Context saving
  - a) Stop DMA transfers on the IN FIFO by clearing the DIEN bit in the CRYP\_DMACR register.
  - b) Wait until both the IN and OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP\_SR register) and the BUSY bit is cleared.
  - c) Stop DMA transfers on the OUT FIFO by writing the DOEN bit to 0 in the CRYP\_DMACR register and clear the CRYPEN bit.
  - d) Save the current configuration (bits [9:2] and bits 19 in the CRYP\_CR register) and, if not in ECB mode, the initialization vectors. The key value must already be available in the memory. When needed, save the DMA status (pointers for IN and OUT messages, number of remaining bytes, etc.).

Additional bits should be saved when GCM/GMAC or CCM/CMAC algorithms are used:

    - bits [17:16] in the CRYP\_CR register
    - context swap registers:  
CRYP\_CSGCMCCM0..7 for GCM/GMAC or CCM/CMAC algorithm  
CRYP\_CSGCM0..7 for GCM/GMAC algorithm.
2. Configure and execute the other processing.
3. Context restoration
  - a) Configure the processor as in [Section 23.3.6: Procedure to perform an encryption or a decryption on page 744](#), *Initialization* with the saved configuration. For the AES-ECB or AES-CBC decryption, the key must be prepared again.
  - b) If needed, reconfigure the DMA controller to transfer the rest of the message.
  - c) Enable the processor by setting the CRYPEN bit and, the DMA requests by setting the DIEN and DOEN bits.

### Case of the TDES

Context swapping can be done in the TDES in the same way as in the AES. But as the input FIFO can contain up to 4 unprocessed blocks and as the processing duration per block is higher, it can be faster in certain cases to interrupt the processing without waiting for the IN FIFO to be empty.

1. Context saving
  - a) Stop DMA transfers on the IN FIFO by clearing the DIEN bit in the CRYP\_DMACR register.
  - b) Disable the processor by clearing the CRYPEN bit (the processing will stop at the end of the current block).
  - c) Wait until the OUT FIFO is empty (OFNE=0 in the CRYP\_SR register) and the BUSY bit is cleared.
  - d) Stop DMA transfers on the OUT FIFO by writing the DOEN bit to 0 in the CRYP\_DMACR register.
  - e) Save the current configuration (bits [9:2] and bits 19 in the CRYP\_CR register) and, if not in ECB mode, the initialization vectors. The key value must already be available in the memory. When needed, save the DMA status (pointers for IN and OUT messages, number of remaining bytes, etc.). Read back the data loaded in

the IN FIFO that have not been processed and save them in the memory until the FIFO is empty.

*Note:* In GCM/GMAC or CCM/CMAC mode, bits [17:16] of the CRYP\_CR register should also be saved.

2. Configure and execute the other processing.
3. Context restoration
  - a) Configure the processor as in [Section 23.3.6: Procedure to perform an encryption or a decryption on page 744, Initialization](#) with the saved configuration. For the AES-ECB or AES-CBC decryption, the key must be prepared again.
  - b) Write the data that were saved during context saving into the IN FIFO.
  - c) If needed, reconfigure the DMA controller to transfer the rest of the message.
  - d) Enable the processor by setting the CRYPEN bit and, the DMA requests by setting the DIEN and DOEN bits.

## 23.4 CRYP interrupts

There are two individual maskable interrupt sources generated by the CRYP. These two sources are combined into a single interrupt signal, which is the only interrupt signal from the CRYP that drives the NVIC (nested vectored interrupt controller). This combined interrupt, which is an OR function of the individual masked sources, is asserted if any of the individual interrupts listed below is asserted and enabled.

You can enable or disable the interrupt sources individually by changing the mask bits in the CRYP\_IMSCR register. Setting the appropriate mask bit to '1' enables the interrupt.

The status of the individual interrupt sources can be read either from the CRYP\_RISR register, for raw interrupt status, or from the CRYP\_MISR register, for the masked interrupt status.

### Output FIFO service interrupt - OUTMIS

The output FIFO service interrupt is asserted when there is one or more (32-bit word) data items in the output FIFO. This interrupt is cleared by reading data from the output FIFO until there is no valid (32-bit) word left (that is, the interrupt follows the state of the OFNE (output FIFO not empty) flag).

The output FIFO service interrupt OUTMIS is NOT enabled with the CRYP enable bit. Consequently, disabling the CRYP will not force the OUTMIS signal low if the output FIFO is not empty.

### Input FIFO service interrupt - INMIS

The input FIFO service interrupt is asserted when there are less than four words in the input FIFO. It is cleared by performing write operations to the input FIFO until it holds four or more words.

The input FIFO service interrupt INMIS is enabled with the CRYP enable bit. Consequently, when CRYP is disabled, the INMIS signal is low even if the input FIFO is empty.

Figure 231. CRYP interrupt mapping diagram

## 23.5 CRYP DMA interface

The cryptographic processor provides an interface to connect to the DMA controller. The DMA operation is controlled through the CRYP DMA control register, CRYP\_DMCCR.

The burst and single transfer request signals are not mutually exclusive. They can both be asserted at the same time. For example, when there are 6 words available in the OUT FIFO, the burst transfer request and the single transfer request are asserted. After a burst transfer of 4 words, the single transfer request only is asserted to transfer the last 2 available words. This is useful for situations where the number of words left to be received in the stream is less than a burst.

Each request signal remains asserted until the relevant DMA clear signal is asserted. After the request clear signal is deasserted, a request signal can become active again, depending on the above described conditions. All request signals are deasserted if the CRYP peripheral is disabled or the DMA enable bit is cleared (DIEN bit for the IN FIFO and DOEN bit for the OUT FIFO in the CRYP\_DMCCR register).

**Note:** *The DMA controller must be configured to perform burst of 4 words or less. Otherwise some data could be lost.*

*In order to let the DMA controller empty the OUT FIFO before filling up the IN FIFO, the OUTDMA channel should have a higher priority than the INDMA channel.*

## 23.6 CRYP registers

The cryptographic core is associated with several control and status registers, eight key registers and four initialization vectors registers.

### 23.6.1 CRYP control register (CRYP\_CR) for STM32F415/417xx

Address offset: 0x00

Reset value: 0x0000 0000

|          |        |          |    |    |    |         |    |          |    |               |    |    |         |      |      |

Bits 31:18 Reserved, must be kept at reset value

Bits 17:16 Reserved, must be kept at reset value

Bit 15 **CRYPEN**: Cryptographic processor enable

0: CRYP processor is disabled

1: CRYP processor is enabled

*Note: The CRYPEN bit is automatically cleared by hardware when the key preparation process ends (ALGOMODE=111b) or GCM\_CCM init Phase*

Bit 14 **FFLUSH**: FIFO flush

When CRYPEN = 0, writing this bit to 1 flushes the IN and OUT FIFOs (that is read and write pointers of the FIFOs are reset. Writing this bit to 0 has no effect.

When CRYPEN = 1, writing this bit to 0 or 1 has no effect.

Reading this bit always returns 0.

Bits 13:10 Reserved, must be kept at reset value

Bits 9:8 **KEYSIZE[1:0]**: Key size selection (AES mode only)

This bitfield defines the bit-length of the key used for the AES cryptographic core. This bitfield is 'don't care' in the DES or TDES modes.

00: 128 bit key length

01: 192 bit key length

10: 256 bit key length

11: Reserved, do not use this value

Bits 7:6 **DATATYPE[1:0]**: Data type selection

This bitfield defines the format of data entered in the CRYP\_DIN register (refer to [Section 23.3.3: Data type](#)).

00: 32-bit data. No swapping of each word. First word pushed into the IN FIFO (or popped off the OUT FIFO) forms bits 1...32 of the data block, the second word forms bits 33...64.

01: 16-bit data, or half-word. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 2 half-words, which are swapped with each other.

10: 8-bit data, or bytes. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 4 bytes, which are swapped with each other.

11: bit data, or bit-string. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 32 bits (1st bit of the string at position 0), which are swapped with each other.

Bits 5:3 **ALGOMODE[2:0]**: Algorithm mode

000: TDES-ECB (triple-DES Electronic codebook): no feedback between blocks of data. Initialization vectors (CRYP\_IV0(L/R)) are not used, three key vectors (K1, K2, and K3) are used (K0 is not used).

001: TDES-CBC (triple-DES Cipher block chaining): output block is XORed with the subsequent input block before its entry into the algorithm. Initialization vectors (CRYP\_IV0(L/R)) must be initialized, three key vectors (K1, K2, and K3) are used (K0 is not used).

010: DES-ECB (simple DES Electronic codebook): no feedback between blocks of data. Initialization vectors (CRYP\_IV0(L/R)) are not used, only one key vector (K1) is used (K0, K2, K3 are not used).

011: DES-CBC (simple DES Cipher block chaining): output block is XORed with the subsequent input block before its entry into the algorithm. Initialization vectors (CRYP\_IV0(L/R)) must be initialized. Only one key vector (K1) is used (K0, K2, K3 are not used).

100: AES-ECB (AES Electronic codebook): no feedback between blocks of data. Initialization vectors (CRYP\_IV0(L/R)...1(L/R)) are not used. All four key vectors (K0...K3) are used.

101: AES-CBC (AES Cipher block chaining): output block is XORed with the subsequent input block before its entry into the algorithm. Initialization vectors (CRYP\_IV0(L/R)...1(L/R)) must be initialized. All four key vectors (K0...K3) are used.

110: AES-CTR (AES counter mode): output block is XORed with the subsequent input block before its entry into the algorithm. Initialization vectors (CRYP\_IV0(L/R)...1(L/R)) must be initialized. All four key vectors (K0...K3) are used. CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that will be XORed with the plaintext or cipher in input. Thus, ALGODIR is don't care when ALGOMODE = 110b, and the key must NOT be unrolled (prepared) for decryption.

111: AES key preparation for decryption mode. Writing this value when CRYPEN = 1 immediately starts an AES round for key preparation. The secret key must have previously been loaded into the K0...K3 registers. The BUSY bit in the CRYP\_SR register is set during the key preparation. After key processing, the resulting key is copied back into the K0...K3 registers, and the BUSY bit is cleared.

Bit 2 **ALGODIR**: Algorithm direction

0: Encrypt

1: Decrypt

Bits 1:0 Reserved, must be kept at reset value

**Note:** Writing to the KEYSIZE, DATATYPE, ALGOMODE and ALGODIR bits while BUSY=1 has no effect. These bits can only be configured when BUSY=0.  
The FFLUSH bit has to be set only when BUSY=0. If not, the FIFO is flushed, but the block being processed may be pushed into the output FIFO just after the flush operation, resulting in a nonempty FIFO condition.

### 23.6.2 CRYP control register (CRYP\_CR) for STM32F415/417xx

Address offset: 0x00

Reset value: 0x0000 0000

|          |        |          |    |    |    |         |    |          |    |               |    |                     |         |           |    |

Bits 31:20 Reserved, forced by hardware to 0.

Bit 18 Reserved, forced by hardware to 0.

Bits 17:16 GCM\_CCMPH[1:0]: no effect if “GCM or CCM algorithm” is not set

00: GCM\_CCM init Phase

01: GCM\_CCM header phase

10: GCM\_CCM payload phase

11: GCM\_CCM final phase

Bit 15 **CRYPEN**: Cryptographic processor enable

0: CRYP processor is disabled

1: CRYP processor is enabled

*Note: The CRYPEN bit is automatically cleared by hardware when the key preparation process ends (ALGOMODE=111b) or GCM\_CCM init Phase*

Bit 14 **FFLUSH**: FIFO flush

When CRYPEN = 0, writing this bit to 1 flushes the IN and OUT FIFOs (that is read and write pointers of the FIFOs are reset. Writing this bit to 0 has no effect. When CRYPEN = 1, writing this bit to 0 or 1 has no effect.

Reading this bit always returns 0.

Bits 13:10 Reserved, forced by hardware to 0.

Bits 9:8 **KEYSIZE[1:0]**: Key size selection (AES mode only)

This bitfield defines the bit-length of the key used for the AES cryptographic core. This bitfield is ‘don’t care’ in the DES or TDES modes.

00: 128 bit key length

01: 192 bit key length

10: 256 bit key length

11: Reserved, do not use this value

Bits 7:6 **DATATYPE[1:0]**: Data type selection

This bitfield defines the format of data entered in the CRYP\_DIN register (refer to [Section 23.3.3: Data type](#)).

00: 32-bit data. No swapping of each word. First word pushed into the IN FIFO (or popped off the OUT FIFO) forms bits 1...32 of the data block, the second word forms bits 33...64.

01: 16-bit data, or half-word. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 2 half-words, which are swapped with each other.

10: 8-bit data, or bytes. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 4 bytes, which are swapped with each other.

11: bit data, or bit-string. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 32 bits (1st bit of the string at position 0), which are swapped with each other.

Bits 19 and 5:3 **ALGOMODE[3:0]**: Algorithm mode

0000: TDES-ECB (triple-DES Electronic codebook): no feedback between blocks of data. Initialization vectors (CRYP\_IV0(L/R)) are not used, three key vectors (K1, K2, and K3) are used (K0 is not used).

0001: TDES-CBC (triple-DES Cipher block chaining): output block is XORed with the subsequent input block before its entry into the algorithm. Initialization vectors (CRYP\_IV0(L/R)) must be initialized, three key vectors (K1, K2, and K3) are used (K0 is not used).

0010: DES-ECB (simple DES Electronic codebook): no feedback between blocks of data. Initialization vectors (CRYP\_IV0(L/R)) are not used, only one key vector (K1) is used (K0, K2, K3 are not used).

0011: DES-CBC (simple DES Cipher block chaining): output block is XORed with the subsequent input block before its entry into the algorithm. Initialization vectors (CRYP\_IV0(L/R)) must be initialized. Only one key vector (K1) is used (K0, K2, K3 are not used).

0100: AES-ECB (AES Electronic codebook): no feedback between blocks of data. Initialization vectors (CRYP\_IV0(L/R)...1(L/R)) are not used. All four key vectors (K0...K3) are used.

0101: AES-CBC (AES Cipher block chaining): output block is XORed with the subsequent input block before its entry into the algorithm. Initialization vectors (CRYP\_IV0(L/R)...1(L/R)) must be initialized. All four key vectors (K0...K3) are used.

0110: AES-CTR (AES Counter mode): output block is XORed with the subsequent input block before its entry into the algorithm. Initialization vectors (CRYP\_IV0(L/R)...1(L/R)) must be initialized. All four key vectors (K0...K3) are used. CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that will be XORed with the plaintext or cipher in input. Thus, ALGODIR is don't care when ALGOMODE = 110b, and the key must NOT be unrolled (prepared) for decryption.

0111: AES key preparation for decryption mode. Writing this value when CRYPEN = 1 immediately starts an AES round for key preparation. The secret key must have previously been loaded into the K0...K3 registers. The BUSY bit in the CRYP\_SR register is set during the key preparation. After key processing, the resulting key is copied back into the K0...K3 registers, and the BUSY bit is cleared.

1000: Galois Counter Mode (GCM). This algorithm mode is also used for the GMAC algorithm.

1001: Counter with CBC-MAC (CCM). This algorithm mode is also used for the CMAC algorithm.

Bit 2 **ALGODIR**: Algorithm direction

0: Encrypt

1: Decrypt

Bits 1:0 Reserved, must be kept to 0.

**Note:** Writing to the KEYSIZE, DATATYPE, ALGOMODE and ALGODIR bits while BUSY=1 has no effect. These bits can only be configured when BUSY=0.  
The FFLUSH bit has to be set only when BUSY=0. If not, the FIFO is flushed, but the block being processed may be pushed into the output FIFO just after the flush operation, resulting in a nonempty FIFO condition.

### 23.6.3 CRYP status register (CRYP\_SR)

Address offset: 0x04

Reset value: 0x0000 0003

|          |    |    |    |    |    |    |    |    |    |    |      |      |      |      |      |
|----------|----|----|----|----|----|----|----|----|----|----|------|------|------|------|------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20   | 19   | 18   | 17   | 16   |
| Reserved |    |    |    |    |    |    |    |    |    |    |      |      |      |      |      |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4    | 3    | 2    | 1    | 0    |
| Reserved |    |    |    |    |    |    |    |    |    |    | BUSY | OFFU | OFNE | IFNF | IFEM |
|          |    |    |    |    |    |    |    |    |    |    | r    | r    | r    | r    | r    |

Bits 31:5 Reserved, must be kept at reset value

Bit 4 **BUSY**: Busy bit

0: The CRYP Core is not processing any data. The reason is either that:

- the CRYP core is disabled (CRYPEN=0 in the CRYP\_CR register) and the last processing has completed, or
- The CRYP core is waiting for enough data in the input FIFO or enough free space in the output FIFO (that is in each case at least 2 words in the DES, 4 words in the AES).

1: The CRYP core is currently processing a block of data or a key preparation (for AES decryption).

Bit 3 **OFFU**: Output FIFO full

- 0: Output FIFO is not full
- 1: Output FIFO is full

Bit 2 **OFNE**: Output FIFO not empty

- 0: Output FIFO is empty
- 1: Output FIFO is not empty

Bit 1 **IFNF**: Input FIFO not full

- 0: Input FIFO is full
- 1: Input FIFO is not full

Bit 0 **IFEM**: Input FIFO empty

- 0: Input FIFO is not empty
- 1: Input FIFO is empty

### 23.6.4 CRYP data input register (CRYP\_DIN)

Address offset: 0x08

Reset value: 0x0000 0000

The CRYP\_DIN register is the data input register. It is 32-bit wide. It is used to enter up to four 64-bit (TDES) or two 128-bit (AES) plaintext (when encrypting) or ciphertext (when decrypting) blocks into the input FIFO, one 32-bit word at a time.

The first word written into the FIFO is the MSB of the input block. The LSB of the input block is written at the end. Disregarding the data swapping, this gives:

- In the DES/TDES modes: a block is a sequence of bits numbered from bit 1 (leftmost bit) to bit 64 (rightmost bit). Bit 1 corresponds to the MSB (bit 31) of the first word entered into the FIFO, bit 64 corresponds to the LSB (bit 0) of the second word entered into the FIFO.
- In the AES mode: a block is a sequence of bits numbered from 0 (leftmost bit) to 127 (rightmost bit). Bit 0 corresponds to the MSB (bit 31) of the first word written into the FIFO, bit 127 corresponds to the LSB (bit 0) of the 4th word written into the FIFO.

To fit different data sizes, the data written in the CRYP\_DIN register can be swapped before being processed by configuring the DATATYPE bits in the CRYP\_CR register. Refer to [Section 23.3.3: Data type on page 739](#) for more details.

When CRYP\_DIN register is written to, the data are pushed into the input FIFO. When at least two 32-bit words in the DES/TDES mode (or four 32-bit words in the AES mode) have been pushed into the input FIFO, and when at least 2 words are free in the output FIFO, the CRYP engine starts an encrypting or decrypting process. This process takes two 32-bit words in the DES/TDES mode (or four 32-bit words in the AES mode) from the input FIFO and delivers two 32-bit words (or 4, respectively) to the output FIFO per process round.

When CRYP\_DIN register is read:

- If CRYPEN = 0, the FIFO is popped, and then the data present in the Input FIFO are returned, from the oldest one (first reading) to the newest one (last reading). The IFEM flag must be checked before each read operation to make sure that the FIFO is not empty.
- if CRYPEN = 1, an undefined value is returned.

After the CRYP\_DIN register has been read once or several times, the FIFO must be flushed by setting the FFLUSH bit prior to processing new data.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATAIN |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
| 15     | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATAIN |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| rw     | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:0 **DATAIN**: Data input

Read = returns Input FIFO content if CRYPEN = 0, else returns an undefined value.

Write = Input FIFO is written.

### 23.6.5 CRYP data output register (CRYP\_DOUT)

Address offset: 0x0C

Reset value: 0x0000 0000

The CRYP\_DOUT register is the data output register. It is read-only and 32-bit wide. It is used to retrieve up to four 64-bit (TDES mode) or two 128-bit (AES mode) ciphertext (when encrypting) or plaintext (when decrypting) blocks from the output FIFO, one 32-bit word at a time.

Like for the input data, the MSB of the output block is the first word read from the output FIFO. The LSB of the output block is read at the end. Disregarding data swapping, this gives:

- In the DES/TDES modes: Bit 1 (leftmost bit) corresponds to the MSB (bit 31) of the first word read from the FIFO, bit 64 (rightmost bit) corresponds to the LSB (bit 0) of the second word read from the FIFO.
- In the AES mode: Bit 0 (leftmost bit) corresponds to the MSB (bit 31) of the first word read from the FIFO, bit 127 (rightmost bit) corresponds to the LSB (bit 0) of the 4th word read from the FIFO.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYP\_CR register. Refer to [Section 23.3.3: Data type on page 739](#) for more details.

When CRYP\_DOUT register is read, the last data entered into the output FIFO (pointed to by the read pointer) is returned.

|         |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31      | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| DATAOUT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r       | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
| 15      | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
| DATAOUT |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r       | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |

Bits 31:0 **DATAOUT**: Data output

Read = returns output FIFO content.

Write = No effect.

### 23.6.6 CRYP DMA control register (CRYP\_DMACR)

Address offset: 0x10

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |      |      |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|------|------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18   | 17   | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |      |      |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2    | 1    | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    | DOEN | DIEN |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    | rw   | rw   |    |

Bits 31:2 Reserved, must be kept at reset value

Bit 1 **DOEN**: DMA output enable

0: DMA for outgoing data transfer is disabled

1: DMA for outgoing data transfer is enabled

Bit 0 **DIEN**: DMA input enable

0: DMA for incoming data transfer is disabled

1: DMA for incoming data transfer is enabled

### 23.6.7 CRYP interrupt mask set/clear register (CRYP\_IMSCR)

Address offset: 0x14

Reset value: 0x0000 0000

The CRYP\_IMSCR register is the interrupt mask set or clear register. It is a read/write register. On a read operation, this register gives the current value of the mask on the relevant interrupt. Writing 1 to the particular bit sets the mask, enabling the interrupt to be read. Writing 0 to this bit clears the corresponding mask. All the bits are cleared to 0 when the peripheral is reset.

|          |    |    |    |    |    |    |    |    |    |    |    |    |       |      |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|-------|------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18    | 17   | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |       |      |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2     | 1    | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    | OUTIM | INIM |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    | rw    | rw   |    |

Bits 31:2 Reserved, must be kept at reset value

Bit 1 **OUTIM**: Output FIFO service interrupt mask

0: Output FIFO service interrupt is masked

1: Output FIFO service interrupt is not masked

Bit 0 **INIM**: Input FIFO service interrupt mask

0: Input FIFO service interrupt is masked

1: Input FIFO service interrupt is not masked

### 23.6.8 CRYP raw interrupt status register (CRYP\_RISR)

Address offset: 0x18

Reset value: 0x0000 0001

The CRYP\_RISR register is the raw interrupt status register. It is a read-only register. On a read, this register gives the current raw status of the corresponding interrupt prior to masking. A write has no effect.

|          |    |    |    |    |    |    |    |    |    |    |    |    |        |       |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|--------|-------|----|

Bits 31:2 Reserved, must be kept at reset value

Bit 1 **OUTRIS**: Output FIFO service raw interrupt status

Gives the raw interrupt state prior to masking of the output FIFO service interrupt.

0: Raw interrupt not pending

1: Raw interrupt pending

Bit 0 **INRIS**: Input FIFO service raw interrupt status

Gives the raw interrupt state prior to masking of the Input FIFO service interrupt.

0: Raw interrupt not pending

1: Raw interrupt pending

### 23.6.9 CRYP masked interrupt status register (CRYP\_MISR)

Address offset: 0x1C

Reset value: 0x0000 0000

The CRYP\_MISR register is the masked interrupt status register. It is a read-only register. On a read, this register gives the current masked status of the corresponding interrupt prior to masking. A write has no effect.

|          |    |    |    |    |    |    |    |    |    |    |    |    |        |       |    |

| Reserved |    |    |    |    |    |    |    |    |    |    |    |    | OUTMIS | INMIS |    |
|          |    |    |    |    |    |    |    |    |    |    |    |    | r      | r     |    |

Bits 31:2 Reserved, must be kept at reset value

Bit 1 **OUTMIS**: Output FIFO service masked interrupt status

Gives the interrupt state after masking of the output FIFO service interrupt.

0: Interrupt not pending

1: Interrupt pending

Bit 0 **INMIS**: Input FIFO service masked interrupt status

Gives the interrupt state after masking of the input FIFO service interrupt.

0: Interrupt not pending

1: Interrupt pending when CRYPEN = 1

## 23.6.10 CRYP key registers (CRYP\_K0...3(L/R)R)

Address offset: 0x20 to 0x3C

Reset value: 0x0000 0000

These registers contain the cryptographic keys.

In the TDES mode, keys are 64-bit binary values (number from left to right, that is the leftmost bit is bit 1), named K1, K2 and K3 (K0 is not used), each key consists of 56 information bits and 8 parity bits. The parity bits are reserved for error detection purposes and are not used by the current block. Thus, bits 8, 16, 24, 32, 40, 48, 56 and 64 of each 64-bit key value  $K_x[1:64]$  are not used.

In the AES mode, the key is considered as a single 128-, 192- or 256-bit long bit sequence,  $k_0k_1k_2...k_{127/191/255}$  ( $k_0$  being the leftmost bit). The AES key is entered into the registers as follows:

- for AES-128:  $k_0..k_{127}$  corresponds to  $b_{127}..b_0$  ( $b_{255}..b_{128}$  are not used),
- for AES-192:  $k_0..k_{191}$  corresponds to  $b_{191}..b_0$  ( $b_{255}..b_{192}$  are not used),
- for AES-256:  $k_0..k_{255}$  corresponds to  $b_{255}..b_0$ .

In any case  $b_0$  is the rightmost bit.

**Note:** Write accesses to these registers are disregarded when the cryptographic processor is busy (bit *BUSY* = 1 in the *CRYP\_SR* register).

**23.6.11 CRYP initialization vector registers (CRYP\_IV0...1(L/R)R)**

Address offset: 0x40 to 0x4C

Reset value: 0x0000 0000

The *CRYP\_IV0...1(L/R)R* are the left-word and right-word registers for the initialization vector (64 bits for DES/TDES and 128 bits for AES) and are used in the CBC (Cipher block chaining) and Counter (CTR) modes. After each computation round of the TDES or AES Core, the *CRYP\_IV0...1(L/R)R* registers are updated as described in [Section : DES and TDES Cipher block chaining \(DES/TDES-CBC\) mode on page 726](#), [Section : AES Cipher block chaining \(AES-CBC\) mode on page 730](#) and [Section : AES counter mode \(AES-CTR\) mode on page 732](#).

IV0 is the leftmost bit whereas IV63 (DES, TDES) or IV127 (AES) are the rightmost bits of the initialization vector. IV1(L/R)R is used only in the AES.

**Note:** In DES/3DES modes, only CRYP\_IV0(L/R) is used.

Write access to these registers are disregarded when the cryptographic processor is busy (bit BUSY = 1 in the CRYP\_SR register).

### 23.6.12 CRYP context swap registers (CRYP\_CSGCMCCM0..7R and CRYP\_CSGCM0..7R) for STM32F42xxx and STM32F43xxx

Address offset:

- CRYP\_CSGCMCCM0..7: 0x050 to 0x06C: used for GCM/GMAC or CCM/CMAC algorithm only
- CRYP\_CSGCM0..7: 0x070 to 0x08C: used for GCM/GMAC algorithm only

Reset value: 0x0000 0000

These registers contain the complete internal register states of the CRYP processor when the GCM/GMAC or CCM/CMAC algorithm is selected. They are useful when a context swap has to be performed because a high-priority task needs the cryptographic processor while it is already in use by another task.

When such an event occurs, the CRYP\_CSGCMCCM0..7R and CRYP\_CSGCM0..7R (in GCM/GMAC mode) or CRYP\_CSGCMCCM0..7R (in CCM/CMAC mode) registers have to be read and the values retrieved have to be saved in the system memory space. The cryptographic processor can then be used by the preemptive task, and when the cryptographic computation is complete, the saved context can be read from memory and written back into the corresponding context swap registers.

*Note: These registers are used only when GCM/GMAC or CCM/CMAC algorithm mode is selected.*

## 24 Random number generator (RNG)

This section applies to the whole STM32F4xx family, unless otherwise specified.

### 24.1 RNG introduction

The RNG processor is a random number generator, based on a continuous analog noise, that provides a random 32-bit value to the host when read.

The RNG passed the FIPS PUB 140-2 (2001 October 10) tests with a success ratio of 99%.

### 24.2 RNG main features

- It delivers 32-bit random numbers, produced by an analog generator
- 40 periods of the RNG\_CLK clock signal between two consecutive random numbers
- Monitoring of the RNG entropy to flag abnormal behavior (generation of stable values, or of a stable sequence of values)
- It can be disabled to reduce power consumption

### 24.3 RNG functional description

[Figure 232](#) shows the RNG block diagram.

**Figure 232. Block diagram**

1. For more details about RNG Clock (RNG\_CLK) source, please refer to [Section 6: Reset and clock control for STM32F42xxx and STM32F43xxx \(RCC\)](#) and [Section 7: Reset and clock control for STM32F405xx/07xx and STM32F415xx/17xx\(RCC\)](#).

The random number generator implements an analog circuit. This circuit generates seeds that feed a linear feedback shift register (RNG\_LFSR) in order to produce 32-bit random numbers.

The analog circuit is made of several ring oscillators whose outputs are XORed to generate the seeds. The RNG\_LFSR is clocked by a dedicated clock (RNG\_CLK) at a constant frequency, so that the quality of the random number is independent of the HCLK frequency. The contents of the RNG\_LFSR are transferred into the data register (RNG\_DR) when a significant number of seeds have been introduced into the RNG\_LFSR.

In parallel, the analog seed and the dedicated RNG\_CLK clock are monitored. Status bits (in the RNG\_SR register) indicate when an abnormal sequence occurs on the seed or when the frequency of the RNG\_CLK clock is too low. An interrupt can be generated when an error is detected.

### 24.3.1 Operation

To run the RNG, follow the steps below:

1. Enable the interrupt if needed (to do so, set the IE bit in the RNG\_CR register). An interrupt is generated when a random number is ready or when an error occurs.
2. Enable the random number generation by setting the RNGEN bit in the RNG\_CR register. This activates the analog part, the RNG\_LFSR and the error detector.
3. At each interrupt, check that no error occurred (the SEIS and CEIS bits should be '0' in the RNG\_SR register) and that a random number is ready (the DRDY bit is '1' in the RNG\_SR register). The contents of the RNG\_DR register can then be read.

As required by the FIPS PUB (Federal Information Processing Standard Publication) 140-2, the first random number generated after setting the RNGEN bit should not be used, but saved for comparison with the next generated random number. Each subsequent generated random number has to be compared with the previously generated number. The test fails if any two compared numbers are equal (continuous random number generator test).

### 24.3.2 Error management

#### If the CEIS bit is read as '1' (clock error)

In the case of a clock, the RNG is no more able to generate random numbers because the RNG\_CLK clock is not correct. Check that the clock controller is correctly configured to provide the RNG clock and clear the CEIS bit. The RNG can work when the CEIS bit is '0'. The clock error has no impact on the previously generated random numbers, and the RNG\_DR register contents can be used.

#### If the SEIS bit is read as '1' (seed error)

In the case of a seed error, the generation of random numbers is interrupted for as long as the SEIS bit is '1'. If a number is available in the RNG\_DR register, it must not be used because it may not have enough entropy.

What you should do is clear the SEIS bit, then clear and set the RNGEN bit to reinitialize and restart the RNG.

## 24.4 RNG registers

The RNG is associated with a control register, a data register and a status register. They have to be accessed by words (32 bits).

### 24.4.1 RNG control register (RNG\_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |    |    |    |    |       |          |    |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|-------|----------|----|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18    | 17       | 16 |
| Reserved |    |    |    |    |    |    |    |    |    |    |    |    |       |          |    |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2     | 1        | 0  |
| Reserved |    |    |    |    |    |    |    |    |    |    |    | IE | RNGEN | Reserved |    |
|          |    |    |    |    |    |    |    |    |    |    |    | rw | rw    |          |    |

Bits 31:4 Reserved, must be kept at reset value

Bit 3 **IE**: Interrupt enable

0: RNG Interrupt is disabled

1: RNG Interrupt is enabled. An interrupt is pending as soon as DRDY=1 or SEIS=1 or CEIS=1 in the RNG\_SR register.

Bit 2 **RNGEN**: Random number generator enable

0: Random number generator is disabled

1: random Number Generator is enabled.

Bits 1:0 Reserved, must be kept at reset value

### 24.4.2 RNG status register (RNG\_SR)

Address offset: 0x04

Reset value: 0x0000 0000

|          |    |    |    |    |    |    |    |    |       |       |          |    |      |      |      |
|----------|----|----|----|----|----|----|----|----|-------|-------|----------|----|------|------|------|
| 31       | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22    | 21    | 20       | 19 | 18   | 17   | 16   |
| Reserved |    |    |    |    |    |    |    |    |       |       |          |    |      |      |      |
| 15       | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6     | 5     | 4        | 3  | 2    | 1    | 0    |
| Reserved |    |    |    |    |    |    |    |    | SEIS  | CEIS  | Reserved |    | SECS | CECS | DRDY |
|          |    |    |    |    |    |    |    |    | rc_w0 | rc_w0 |          |    | r    | r    | r    |

Bits 31:3 Reserved, must be kept at reset value

Bit 6 **SEIS**: Seed error interrupt status

This bit is set at the same time as SECS, it is cleared by writing it to 0.

0: No faulty sequence detected

1: One of the following faulty sequences has been detected:

- More than 64 consecutive bits at the same value (0 or 1)
- More than 32 consecutive alternances of 0 and 1 (0101010101...01)

An interrupt is pending if IE = 1 in the RNG\_CR register.

Bit 5 **CEIS**: Clock error interrupt status

This bit is set at the same time as CECS, it is cleared by writing it to 0.

0: The RNG\_CLK clock was correctly detected

1: The RNG\_CLK was not correctly detected ( $f_{\text{RNG\_CLK}} < f_{\text{HCLK}}/16$ )

An interrupt is pending if IE = 1 in the RNG\_CR register.

Bits 4:3 Reserved, must be kept at reset value

Bit 2 **SECS**: Seed error current status

0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.

1: One of the following faulty sequences has been detected:

- More than 64 consecutive bits at the same value (0 or 1)
- More than 32 consecutive alternances of 0 and 1 (0101010101...01)

Bit 1 **CECS**: Clock error current status

0: The RNG\_CLK clock has been correctly detected. If the CEIS bit is set, this means that a clock error was detected and the situation has been recovered

1: The RNG\_CLK was not correctly detected ( $f_{\text{RNG\_CLK}} < f_{\text{HCLK}}/16$ ).

Bit 0 **DRDY**: Data ready

0: The RNG\_DR register is not yet valid, no random data is available

1: The RNG\_DR register contains valid random data

*Note: An interrupt is pending if IE = 1 in the RNG\_CR register.*

*Once the RNG\_DR register has been read, this bit returns to 0 until a new valid value is computed.*

### 24.4.3 RNG data register (RNG\_DR)

Address offset: 0x08

Reset value: 0x0000 0000

The RNG\_DR register is a read-only register that delivers a 32-bit random value when read. After being read, this register delivers a new random value after a maximum time of 40 periods of the RNG\_CLK clock. The software must check that the DRDY bit is set before reading the RNDATA value.

|        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 31     | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| RNDATA |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| r      | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  | r  |
